The authority and functions of the medical director vary from group to group, depending more or less on the type, size and history of the group. As has been noted, the medical director of the smaller partnership group tends to be the oldest member, usually one of the founders. He is likely to be responsible for coordination of professional and business matters, supervision of the business manager, and in general for the efficient management of the group. The medical director of the large partnership groups, on the other hand, tends to be a presiding chairman at partnership or executive committee meetings, occasionally with supervisory powers over the younger men in the group, and generally with much less authority than is the case in the smaller groups.

---

[8] The incidence of partnerships among medical groups noted in the present paper, namely, 82 per cent, has apparently remained unchanged since 1939, when 80 per cent of the groups noted at that time were found to be partnerships.[4] Of the medical groups counted in 1932, 60 per cent were partnerships.[3]

[9] Considered as partnerships for the practice of medicine are three incorporated groups in which the physicians, comprising the corporation, placed themselves on an employed salary basis.

[10] Size of group, unless otherwise specified, will have reference to full time physicians, thus: small group, three to five physicians; medium group, six to ten physicians; large group, eleven or more physicians. On occasion, the first two categories will be combined and referred to as smaller groups.

[11] According to a questionnaire survey of medical groups in 1946, 59 per cent of three hundred and sixty-eight groups had a medical director.[12]

The Executive Committee.—The executive committee is primarily an organizational form of the large group. All of the 13 partnerships with an executive committee, of 33 groups for which information on this question was available, were either medium or large in size, usually the latter. The executive committee generally takes the place of the medical director, or, if this office is retained, it is shorn of the powers and functions noted. This pattern does not refer to hospital groups in which an executive committee seems to be merely an advisory body to the medical director.

The vesting of administrative powers in an executive committee does not mean that the partners as a group are not consulted or have no voice in policy; the contrary is usually the case.

The composition of the executive committee may consist of the active founding partners only, or more often, the former plus several other senior partners elected at regular intervals by the whole partnership.

Other Committees.—Occasionally a group may have a number of committees of the partners, instead of an executive committee, each in charge of a different phase of business and professional activities. Some committees are elected by the partnership; others are appointed by a presiding chairman or other comparable figure in the group.

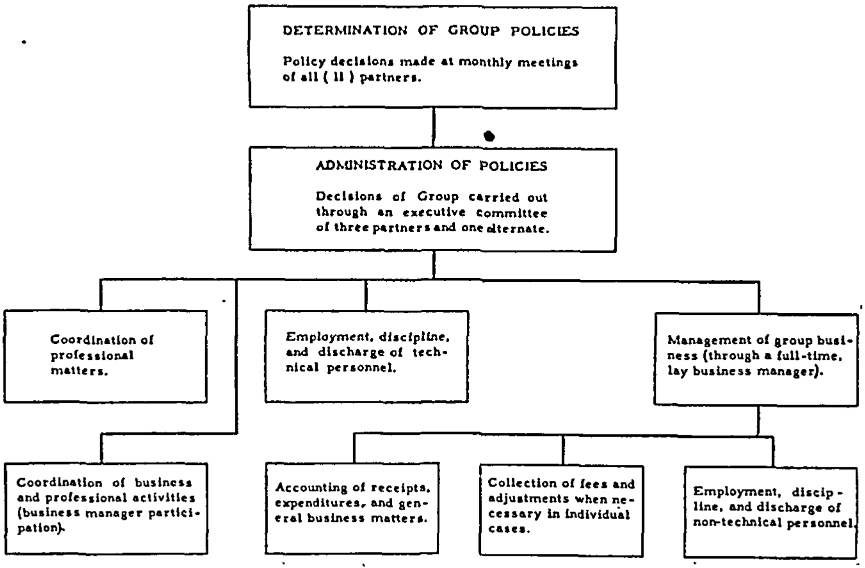
The Business Manager.—Some 79 per cent of 368 medical groups throughout the country in 1946, including both small and large groups, stated that they had a business manager. The concept of a business manager in a medical group apparently runs the gamut from secretary or bookkeeper to the person professionally trained in medical economics and administration. The numerical separation of groups with regard to qualification of the business manager was not feasible. In any case, it may be said that the office is generally held by a layman employed by the group; only occasionally is the business manager a physician or dentist of the staff.

The authority and functions of the business manager vary considerably from group to group, although only rarely does he have any authority in professional matters. More commonly, the role of the business manager is to work under and with the medical director or executive committee in the business administration of the group. He employs and supervises the office personnel and is responsible for collection of fees and a general accounting of receipts and expenditures. He may adjust fees in individual cases when this is deemed necessary. He is a member of committees, although usually with no vote therein, and generally participates in the coordination of business and professional affairs.

Opinions concerning the role of a business manager in group practice were obtained from 163 physicians in the 18 groups studied intensively. Some 65 per cent of the physicians felt that the business manager should not be a partner in the partnership group. A majority stated that the business manager should have no active participation in professional matters; some 42 per cent felt that he should have no vote even in business matters. The physicians of groups having a business manager generally were satisfied with his powers, only 5 per cent stating that the powers of their business manager were excessive.

In brief, the sentiment of group physicians with respect to activities of the business manager would seem to reflect a highly cautious attitude as regards delegation of powers to the business manager. The authority of the business manager in most of the groups studied intensively was in fact definitely circumscribed, particularly so as regards professional matters.

Six physicians in a group would justify the services of a business manager, according to the median response of the 163 physicians queried on this question.



DETERMINATION OF GROUP POLICIES
Policy decisions made at monthly meetings of all (11) partners.
ADMINISTRATION OF POLICIES
Decisions of Group carried out through an executive committee of three partners and one alternate.
Coordination of professional matters.
Employment, discipline, and discharge of technical personnel.
Management of group business (through a full-time, lay business manager).
Coordination of business and professional activities (business manager participation).
Accounting of receipts, expenditures, and general business matters.
Collection of fees and adjustments when necessary in individual cases.
Employment, discipline, and discharge of non-technical personnel.

Fig. 1.—A schematic summary of the functional administration in group A, a characteristic partnership group.

Departmentalization.—Some groups, especially among the larger ones, are organized on a departmental basis. That is, there may be departments of surgery, internal medicine, etc., and even of subspecialties of some of these, usually with several physicians in each department. The division of group physicians in departments is probably a matter of professional convenience in dealing with patients, although the powers and functions of departments may vary considerably in different groups. Even when more or less authority is vested in the department head, the department as such still forms an integral part of the group in general administration.

DISTRIBUTION OF INCOME

Distribution of Income in Groups.—The main mediums of distributing income in medical groups are by share of net, by salary or by a combination of the two. Table 2 shows the mode of income distribution among 102 medical groups. Of the 84 partnership groups, 74 per cent shared their pooled net income among the partners. A fixed salary was the mode of payment to the employed men in most of the 57 partnership groups which employed physicians, although in about 30 per cent of these groups the employed physicians received a share of the net (or a bonus) in addition to salary. Seven of the 102 groups had partners or employed members receiving a percentage of their own intake based on collections or bookings.

TABLE 2.—*Mode of Distribution of Income to Physicians in One Hundred and Two, Medical Groups*

	Composition of Groups			
	Partnership Groups		Employed Physicians	
Mode of Distribution	Partners	Employed Physicians	Single Owner Groups	All Employed Groups *
	Number of Groups			
Total groups	84	57	8	10
Share of pooled net	62	..	..	..
Salary plus share of net †	12	17	4	2
Fixed salary	..	27	1	8
Percentage of own collections	3	2	2	..
No information	7	11	1	..

* This category includes nonprofit voluntary hospital groups, consumer cooperative and industrial groups.

† The share of net in some instances was in the form of a bonus rather than, strictly speaking, a share in the sense of a prearranged percentage of net.

The report of the Bureau of Medical Economics in 1933 did not find any correlation between method of distribution of income and size of group. A suggestion f such a relationship at the present time may be noted in table 3, especially with reference to employed physicians and the fixed salary arrangement, 62 per cent of the large groups in contrast to 35 per cent of the smaller ones providing a fixed salary to their employed staff members. The few groups with physicians receiving a percentage of their own collections or bookings were almost all in the smaller group category.

Income generally varied among members of the groups, the share or salary usually depending on professional value of the physician to the group, especially in terms of experience and competence, as well as on earning capacity of the individual; e.g., book value of work done by the physician. This was the case in 45 of 74 partnership groups for which information was available; in 12 of the groups the partners of the same class received an equal share of the net proceeds, and in 17 groups the income was divided equally among all the partners.

TABLE 3.—*Mode of Distribution of Income in Medical Groups by Size of Group*

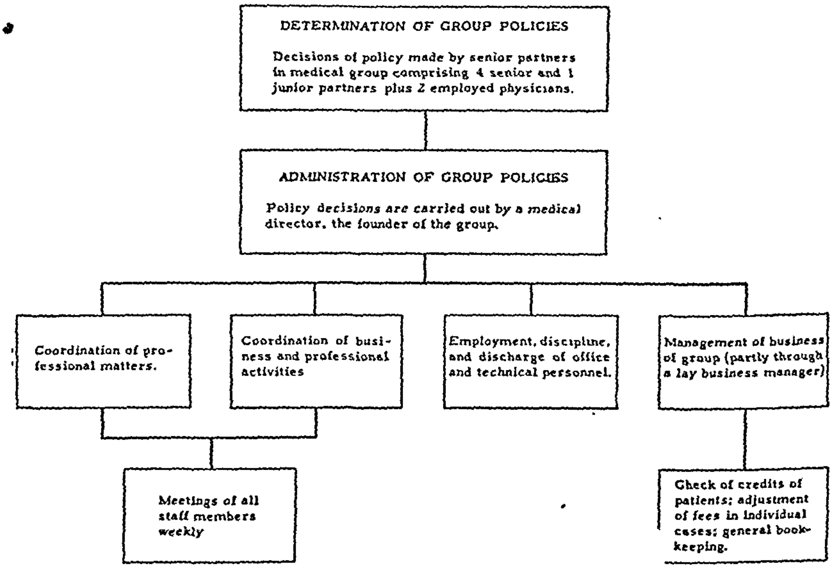
	Partners in		Employed Physicians in	
Mode of Distribution	Smaller Groups *	Large Groups	Smaller Groups	Large Groups
Total groups	54	30	40	35
Share of pooled net	38	24	..	..
Salary plus share of net	7	5	14	9
Fixed salary	..	..	14	22
Percentage of own collections	3	..	3	1
No information	6	1	9	3

* Smaller groups refer to 3 to 10 physicians; large groups to 11 or more physicians.

The sentiment of 163 physicians in 15 medical groups was sampled on questions of distribution of income. Most of the men stated that full partners should receive a salary plus share of net rather than a straight share of net income. Almost half of them felt that even the employed physicians in medical groups should receive a bonus or share of the net in addition to a fixed salary, a feeling expressed more frequently among the younger than the older physicians (60 per cent compared with 38 per cent), perhaps because a relatively larger number of the younger men were in the employed status.

In brief, as represented by this sample of physicians, there seems to be a tendency for physicians in group practice today to want some definitely assured income; that is, a salary in addition to a share of the net proceeds, instead of merely a percentage of the pooled net.

Partners may receive an equal or a varying share of the net proceeds, and the question was asked as to which method was preferred. Half of the physicians stated that there should be variation in share of net income among the partners; 37 per cent of them, on the other hand, noted that income should be distributed equally to members of each class. It is of some interest that relatively more of the physicians of the smaller groups than those in the large ones expressed the desire for equality of income distribution (54 per cent versus 29 per cent).



DETERMINATION OF GROUP POLICIES
Decisions of policy made by senior partners in medical group comprising 4 senior and 1 junior partners plus 2 employed physicians.
ADMINISTRATION OF GROUP POLICIES
Policy decisions are carried out by a medical director, the founder of the group.
Coordination of professional matters.
Coordination of business and professional activities
Employment, discipline, and discharge of office and technical personnel.
Management of business of group (partly through a lay business manager)
Meetings of all staff members weekly
Check of credits of patients; adjustment of fees in individual cases; general bookkeeping.

Fig. 2.—A schematic summary of the functional administration in group B, a characteristic partnership group.

The physicians were also requested to check off on a list those factors which they felt should be considered in determining the income, whether it be by salary or share, of a physician in group practice. The physician was not asked his order of choice in the several listed factors. The first five criteria for most of the men were competence, professional value to the group, length of time with the group, experience and training, all of these considerations really being highly interrelated. It is noteworthy that nearly a fourth of the men felt that book value of work done by the individual physician should be one of the factors to be considered in determining salary or share of net income.

The criteria for determining income as stated by the physicians seem much like those mentioned by the medical director or comparable authority as being in actual operation in the respective groups interviewed, and it is not unlikely that the opinions of the individual physicians are largely a reflection of the conditions obtaining in their own groups.

COMMENT

An attempt has been made in the preceding sections to describe existing conditions rather than to pass judgment as to merit or to suggest any ideal mode of group organization. Presumably an approach to the "ideal" would be that type of organization which would assure a harmonious, efficient group, provide an equitable distribution of income, maintain high standards of medical care and in general be conducive to successful survival. It is hardly likely that only one kind of organization or administration would achieve the desired results; the contrary would be expected in view of circumstances peculiar to each group. Also, group practice even on the organizational level is seldom a static phenomenon: groups change in size and composition in the course of time, as do the circumstances surrounding the group, and readjustments are a common occurrence. Central tendencies can be noted, however, and a periodic check of these common characteristics as well as the variations therefrom would seem of manifest importance for any intelligent appraisal of the dynamics of medical group practice.

SUMMARY

A preliminary discussion of questions pertaining to organization for ownership of physical assets, administration and mode of distribution of income in medical groups has been attempted on the basis of interviews of a number of groups.

Most medical groups were found to be partnerships with reference both to practice and ownership, although some 30 per cent of these groups had their holdings incorporated.

The medical director was usually the chief administrative officer of the group, although the larger partnerships tended to have an executive committee take his place in authority and functions. In either case there was usually periodic consultation among the physicians in the group regarding professional and business policies.

Partnership groups often were divided into senior and junior categories, with employed physicians serving a probationary period before achieving partnership status.

Most groups had a lay business manager working under the direction of the medical director or executive committee, exercising greater or less responsibility for administration of the business affairs of the group. An opinion poll of the group physicians concerning the role of a business manager in the group indicated a highly cautious attitude as to delegation of powers to the latter.

Some 74 per cent of the partnership groups shared their pooled income; the employed physicians in partnership groups usually received a fixed salary, many also receiving an additional bonus or even a share of the net income. The division of income within the group was based largely on professional value of the physician to the group as well as his earning capacity. The opinion of group physicians in regard to desirable mode of distribution of income indicated a large sentiment in favor of salary plus share of net for both partners and employed members of the group.

CONGENITAL ABSENCE OF THE VAGINA

VIRGIL S. COUNSELLER, M.D.
Rochester, Minn.

The surgical treatment of congenital absence of the vagina constitutes a most interesting chapter in gynecology. Like the treatment of other anomalies, it has gone through many changes, with successes and failures, and ultimately a method of correction evolves which becomes simple, easy of execution and attended by low mortality and morbidity rates, and which produces a high percentage of good results. There always will be some poor results and even failures in the management of any congenital anomaly by virtue of the defective quality of the tissues with which the surgeon must work.

In this communication I wish to report a group of 76 cases of congenital absence of the vagina, to describe a surgical procedure which I think is adequate and to disclose the results. The patients were seen and treated during the decade ending Dec. 31, 1946. Eight more have been treated during the present year but are not included in this paper. There have been seen, and surgically treated in the clinic, exactly 100 patients, to the present. Patients other than those who are herein reported on were treated by various surgical procedures, in which segments of the intestine or pedicle grafts were utilized.

The incidence of congenital absence of the vagina is not known, but the increasing number of cases of the condition that are being reported causes one to believe that the incidence is much higher than was originally considered. The anomaly was first described in 1572 by Realdus Columbus.[1] Engstadt[2] estimated that vaginal aplasia occurred once in 5,000 births, but Owens[3] reported that only 6 instances of the condition were encountered in more than 500,000 admissions of women to the Charity Hospital in New Orleans, where a fourth of the women admitted were obstetric or gynecologic patients.

EMBRYOLOGIC ASPECTS

There is much controversy among embryologists concerning the development of the vagina. In these various theories partial to total development is said to proceed from (1) the müllerian ducts, (2) the wolffian ducts and (3) the urogenital sinus. In the 8 mm. embryo the müllerian ducts appear as an invagination of the celomic cavity lateral to the upper portion of the wolffian ducts. The caudal portion of the müllerian ducts forms a tube with a solid tip which burrows through the mesenchyma of the urogenital fold, crossing the wolffian ducts anteriorly and at the caudal end of the mesonephron. In the 30 mm. embryo the caudal tips of the müllerian ducts fuse and reach the posterior wall of the urogenital sinus, which is pushed forward, forming the müllerian tubercle. With distal fusion of the müllerian ducts, the uterovaginal canal is formed. The wolffian ducts have kept pace with the müllerian system, but

in the 56 mm. embryo signs of involution begin to appear. At approximately this time there is great intermingling of cells, the urogenital sinus and wolffian and müllerian ducts, and it is in relation to this stage of development that controversy persists as to what group of cells proliferate to predominate in the formation of the vagina. In the 63 mm. embryo the müllerian tubercle gives way to the bilateral sinovaginal bulbs formed by the evagination of the posterior wall of the urogenital sinus. The growing of the sinovaginal bulbs and the transformation of the columnar epithelium to stratified epithelium of the uterovaginal canal (lower portion) merge to form the primitive vaginal plate. The vaginal plate increases in size, and cellular proliferation invades the surrounding mesenchyma. The epithelial activity begins at the caudal end. This proliferation forms a solid vaginal cord. The cells in the center of the solid cord undergo involution and desquamation, thereby forming the vaginal canal which communicates with the cervical canal above and the hymenal foramen below. This latter process appears first in embryos of 150 to 200 mm. in length of trunk (Nagel, 1891[4]).

HISTORICAL DEVELOPMENT

Rectal Transplant.—Sneguireff[5] in 1892 made an incision from the coccyx to the anus and separated the rectum from the coccyx, which was resected. The gut was ligated in two places and divided. The superior segment was sutured to the right of the resected coccyx; the inferior segment was brought down, and its upper end was closed. Two weeks later a second stage was done, in which the perineum was incised and the rectal mucous membrane was sutured to the adjacent parts. In 1910 Popow[1] and, in 1911, Schubert[1] utilized methods for reconstruction similar to those used by Sneguireff.

Ileal Transplant.—Baldwin[6] in 1904 described a method in which the ileum was used as a transplant, but he did not put this method into practice until 1907. He excised a 10 inch (25 cm.) loop of ileum and reunited the bowel by end to end anastomosis. He then tunneled between bladder and rectum, pulled the middle of the excised loop downward, attaching the upper end of one loop around the cervix, and closed the end of the other loop; the abdomen was then closed. With the patient in the lithotomy position and the loop of bowel still held by a forceps, the bowel was opened and cleansed, each limb was packed with iodoform gauze, and the edges of the bowel were attached to the surrounding hymenal margins. After two weeks a clamp was placed on the double barrel, so that the two loops of bowel were converted into one canal. In 1910, Mori[7] modified Baldwin's procedure by using only one loop of bowel, which was sutured to the vaginal introitus.

Labial Grafts.—Jewett[8] in 1904 first utilized labial grafts, but Graves,[9] in 1908, was the one who brought this procedure into favor, by using two labial flaps and two thigh flaps over a glass form. When the skin pouch was nearly completed, the glass form was removed and the flaps were invaginated and sutured to the depth of the vault. Davis and Cron[10] modified Graves' technic by using labial flaps entirely, and made their original perineal incision vertically rather than transversely. Falls,[11] in 1940, cut a disk 2 to 3 cm. in diameter around the introitus; the edges were then undercut and the disk was pushed back by blunt dissection. Four skin flaps from the vulval opening were taken, and their free ends were sewed to the edges of the disk. This skin-lined cavity was packed with gauze daily, and moderate pressure was maintained until healing was complete.

Thigh Graft.—Among the first surgeons to use pedicle grafts from the thigh was Beck,[12] in 1900. His method was a combined abdominoperineal extraperitoneal approach to the vaginal area, in which he placed a tube graft made from pedicle flaps taken from the thigh. Frank and Geist[13] in 1927 modified this method considerably by means of a multiple stage procedure. First, a tube graft was constructed from the thigh with the skin side out, both ends of the tube being left attached to the thigh; later, the distal end was severed and the graft was cut longitudinally and placed over a mold or speculum, with the skin inside. The rectovaginal space was opened and the mold, covered with skin graft, was inserted into the new tract. Eight days later the proximal end was severed from the thigh and sutured to the margins of the vulva. Grad[14] in 1932 introduced a similar method, but did not use a mold or speculum until the graft had been placed in the new vaginal space.

Free Skin Grafts.—Constructing a vagina by means of free skin grafts was first reported in 1872 by Heppner,[15] but it did not attract much attention. However, in 1915 Flynn,[16] after blunt perineal dissection, used a free skin graft from the external genitalia to graft the new tract. This was followed by repeated dilation until complete epithelialization took place. Good results are reported to follow this operation. Kirschner and Wagner,[17] in 1930, reported that they used a rubber sponge prosthesis, covered with Thiersch grafts, which was then placed in the new vaginal cavity. When the prosthesis was later removed, dilatation of the vagina was instituted. McIndoe and Banister,[18] in 1938, reported 1 case in which they had successfully used a Thiersch graft over a vulcanite mold, which was left in place three to six months. They stressed the importance of long-continued use of the mold to prevent contracture of the new tract. Bonney and McIndoe[19] described a unique constructive operation carried out for an 18 year old woman. Abdominal surgical exploration revealed a double uterus with no cervix. One month later the vaginal space was opened and the two uterine bodies were joined over a tube which was covered with a skin graft. A normal vagina was obtained. The authors said that the patient then menstruated regularly. They said that they each had performed about thirty such operations; using a skin-covered mold. In 1944 I reported 35 cases in which I had used this method.[20]

[19] Bonney, V., and McIndoe, A. H.: Unique Constructive Operation, J. Obst. & Gynaec. Brit. Emp. **51:** 24-29 (Feb.) 1944.

Simple Pressure.—Frank,[21] in 1938, devised a method of creating an artificial vagina without operation. He modified this procedure in 1940.[22] Graduated tubes were pushed against the perineum downward and inward half an hour twice a day. The patients came to the office once a week for the first month, and then every other week for two months. After this period of dilatation, Frank said, a permanent vagina was established in which the greatest depth attained was 3½ inches (9 cm.) This would be the ideal method if sufficient depth could be obtained in all cases.

Simple Reconstruction.—This is a method consisting merely of opening the vaginal space and of having it held open by some substance to permit the tract to epithelialize itself without the use of a skin graft. This was first done by Dupuytren [23] in 1817. He used tampons in the dissected tract to maintain patency while epithelialization took place, but the procedure was unsuccessful. Considerable interest in this method was renewed by Wells,[24] who in 1935 packed the vaginal space with petrolatum gauze which was changed every two days. Kanter,[25] in 1935, used iodoform gauze similarly. After several weeks, the patient wore a vaginal dilator for a while. Biopsy showed squamous cell epithelium in the vagina postoperatively. The result in both instances evidently was good. Wharton,[26] in 1938, reported 2 cases in which this method was employed; a mold made of paraffin or balsa wood, covered by a condom, was used. Wharton [26] said in 1 case in which he had used this method ten years prior to the report of 1938 the result was excellent. In the second case the patient did not report to him after one month. This attitude probably meant that she was satisfied with her result.

Wharton [26] at that time expressed the opinion that the epithelium from the urogenital sinus (the lower third part of the vagina) forms a large part of the fetal vagina growing around the müllerian ducts (upper two thirds) and that in both his cases the epithelium arose from the vestibule or rudimentary vagina. In a later report [27] he referred to 12 cases in which the method had been used by seven surgeons, with 8 successes, 3 failures and 1 unknown result. More recently, Wharton [28] has said that he favors use of a Thiersch graft over the mold to hasten epithelialization. He said it decreases the amount of scar formation. He reported 16 cases in which vaginal reconstruction was done at the Johns Hopkins Hospital. Miller, Willson and Collins [29] reported 17 cases of theirs; in 6 of them reconstruction was done without the graft and in 11 the graft was used. These authors thought that superior results were obtained in those cases in which a graft was used, because in such instances the vagina was more soft, pliable and better epithelialized than when a graft was not used.

THE PRESENT STUDY

At the Mayo Clinic we have seen 76 patients with congenital absence of the vagina. For 70 patients the technic of McIndoe was employed, in which a "lucite" mold, covered by a Thiersch skin graft taken from the abdomen or thigh, was used. For 6 patients simple reconstruction was done, in which a "lucite" mold was left in the vaginal tract without a skin graft.

Analysis of Cases.—The age of these patients ranged from 14 to 49 years. Twenty-one were less than 20 years old. Forty-eight were less than 30 years old. Six were less than 40, and 1 was 49 years of age. The last patient whom we treated had undergone a Baldwin operation, performed some years previously, which was a failure. The McIndoe operation was successful. Sixty-six of the patients were single and 10 were married.

Not all the patients were studied for anomalies of the urinary tract, but of those studied, 16 were normal in this respect and 19 had some type of anomaly. Of the 19, 6 had a pelvic kidney, 5 had a solitary kidney, 3 had duplicated ureters or pelves, 2 had pyeloureterectasis, 1 had a malfunctioning kidney, 1 had a solitary fused kidney and 1 previously had undergone nephrectomy for an unknown reason. Four had incomplete development of the uterus and bilateral hematosalpinx and endometriosis. In each instance there was complete absence of the cervix; hence, abdominal hysterectomy was performed. In 1 patient in this group (reported on by Ferris [30]) the cervical canal was opened when the vaginal tract was reconstructed; this was followed by normal menstruation.

RESULTS

Of the 70 patients in whom skin grafts were used, 55 obtained excellent results, although for 2 it was necessary to do a secondary grafting procedure. In 1 of these the graft completely sloughed out during an attack of acute exfoliating dermatitis. For 10 of the patients the result was considered to be fair, since some had granulations which would not epithelialize and produced slight contracture, although 7 of these who are married have said that their sexual relations are entirely normal and satisfactory. In 5 cases the results were considered to be poor or failures; they were due primarily to infection, with incomplete take of grafts, resulting in contracture and stenosis. Three of these patients were uncooperative and refused to wear the mold. Of the 6 patients in whom no graft was used, all have obtained excellent results. The vaginas have completely epithelialized; there are no contractures, and the vaginas are of normal depth and normal mobility. Nineteen patients have been married since their operation; 9 were married before surgical treatment. Hence, 28 of those heard from are married and all, at the time of this report, had normal marital relations. Thirty-two were still single and 16 had not been heard from at the time this paper was written.

COMMENT

Several points of clinical importance concerning patients with congenital absence of the vagina should be stressed. If they do not have abdominal symptoms of menstruation or palpable, painful adnexal masses, there is no need for surgical intervention unless the patient contemplates marriage. The operation will not improve their general health, but if the patient is operated on, she may have a happier outlook on life, knowing that she can be married without subsequent difficulties if the opportunity presents itself. The psychologic attitude and frigid character of a few such patients is such that any idea of their marriage should be discouraged, because the probability of incompatibility and extreme unhappiness is great.

If the patient has a functioning uterus and it is possible to construct a vagina and establish menstruation, as did McIndoe and Banister in their case and Ferris in his case and as was done in a few other cases that have been reported, such an outcome represents the ultimate in success. However, the number of patients in whom this can be done will remain small, because the vast majority of such patients either have no uterus at all or one that has very little functioning endometrium and will require removal to obtain relief of pain. Hematosalpinx and endometriosis probably are associated in such cases. Miller,[31] in a personal communication, said that he had never seen an instance of endometriosis in congenital absence of the uterus and vagina —a pertinent observation in respect to the etiology of endometriosis.

Congenital anomalies of the urinary tract in association with congenital absence of the vagina are of frequent occurrence, so that the upper part of the urinary tract should be investigated prior to any surgical operation to correct the absence of the vagina. When one kidney is ectopic, it usually is in front, or to one side, of the sacrum. In this position it will interfere with the obtaining of proper depth of the vagina, and is likely to be traumatized during sexual relations. Moreover, this ectopic kidney also may be solitary. A fused kidney also may lie in the pelvis. A hydronephrotic kidney in the pelvis has been diagnosed as an ovarian cyst. Removal of such a kidney is not a simple procedure, since it has a fixed position because of the entrance of many anomalous blood vessels at both the upper and lower poles, as well as at the hilus. Anomalous insertion of a ureter or a duplicated ureter into the bladder may result in formation of a ureterovaginal fistula.

The ability of the vaginal tract completely to epithelialize itself without skin graft is of tremendous importance. In enough cases, treatment has been based on this method, with success, to enable one to say that in certain instances a graft is not necessary. The difficulty is to select the patients for whom the grafting procedures should be used. I believe that in those cases in which the vaginal tract can be opened up easily and satisfactorily, without bleeding from the venous plexus on each side near where the uterine vessels ordinarily would enter, and when there is no difficulty in elevating the peritoneum, the grafting procedure probably does not need to be used in the vaginal tract. Where this epithelium comes from, in such an instance, is a debated question, but it probably arises from the lower segment of the vagina and also from some buds of epithelium from remnants of the müllerian ducts. During dissection one of these buds was picked up from beneath the bladder. It was immediately subjected to biopsy, and was found to be squamous epithelium. This epithelialization might be accelerated by administration of estrogenic substances. Ayre[32] took smears from an artificial vagina, in which no graft had been used, and showed the new lining to be reacting in a cyclic manner to ovarian hormones in the same manner as a normal vagina does.

If there is a complete take of a Thiersch graft, it produces an excellent result, provided the mold is worn long enough. Our only difficulty with the Thiersch graft has been that, occasionally, there will be one or more areas in the vagina which are devoid of skin, and it is unlikely that any epithelium will extend from the remaining skin graft to cover the defect. It is usually necessary to regraft these areas. It is of interest, also, to note that granulation rarely occurs in a vagina in which the grafting procedure has not been employed. If, however, granulation does take place in such an instance, the granulations are smaller and are situated in the areas of the bleeding points which occurred during the original dissection.

We believe, therefore, that it is possible to determine at the time the vaginal tract is opened whether or not a skin graft of the Thiersch type will be indicated. If the dissection has been difficult, as frequently is true in a secondary operation, bleeding should be accurately controlled and the tract grafted over a nonirritating mold. If the tract can be easily opened, if there is no bleeding of consequence and if some granular buds of epithelium can be demonstrated, and proved by biopsy, at the reflection of the peritoneum from the base of the bladder, we believe that such a tract will completely epithelialize itself without the need for a graft.

One point to be observed in the subsequent treatment of these patients applies to both methods (that is, use or nonuse of a graft), and that is the "contraction factor." If the factor of contraction in these new vaginal tracts is disregarded, there will be a greater incidence of poor results and failures than if this factor is observed. McIndoe, who is primarily a plastic surgeon, is responsible for pointing this out to us. It is the one point which made the method described by Kirschner and Wagner[17] a successful operation. Hence, I usually refer to this method as the "McIndoe procedure."

McIndoe said that the contraction factor of any canal lined by a Thiersch graft may last three to six months or longer, and that if the mold is removed before this "contraction" disappears, stricture of the new canal will ensue. Most failures or poor results are due to removal of the mold too soon. I have the greatest difficulty in convincing patients and some physicians that the mold must remain in position for at least six months or longer, and that it must be removed only for cleansing purposes or for inspection of the graft. I have had some patients who have worn the mold for two years, during the process of regrafting. In fact, I see no reason why a lightweight mold constructed of a nonirritating substance could not be worn during the entire period of the patient's sexual life, if necessary, to maintain patency. There are other parts of the body where artificial molds and braces are worn as long as the patients concerned live.

[31] Miller, N. F.: Personal communication to the author.

[32] Ayre, J. E.: Cyclic Ovarian Changes in Artificial Vaginal Mucosa, Am. J. Obst. & Gynec. 48: 690-695 (Nov.) 1944.

Perivaginal inflammation also contributes to contraction and shortening if the mold is taken out. It may take two to four months before all of the perivaginal and perirectal cellulitis completely subsides. This element of time is variable; it may be more in respect to some patients than to others. The scarring and contraction of a Thiersch graft also vary among different patients.

If the vagina has not been constructed by means of the grafting procedure, a vaginal mold also is required to be worn until the entire tract has been proved by observation and biopsy to be completely epithelialized. This will require a minimum of four months and perhaps longer.

SUMMARY AND CONCLUSIONS

It would seem that a sufficient number of operations for congenital absence of the vagina utilizing the McIndoe principle, with or without a Thiersch graft, have been performed in this country and abroad to permit recommendation of the procedure as probably the best and simplest procedure for correction of this anomaly. There are, it is true, other methods which will give satisfactory results. This particular method produces a vagina which will be normal in depth, diameter and mobility. The risk of the operation is practically nonexistent. In this series there was no death. The morbidity rate will vary according to the amount of pelvic cellulitis which may occur. The operation technically is simple, and consists only in the careful opening of the vaginal space and the use of a skin-covered mold or use of such a mold without the skin, as the case may be. The principle of mechanical prevention of contraction of the new vaginal tract by means of a mold is the basis for success in every one of these operations. The majority of procedures in which portions of intestine or pedicle flaps are utilized are multiple stage operations, excepting that described by Falls,[11] which appears to be a simple and excellent procedure. I rather doubt that the functional effect which is obtained by the McIndoe operation can be attained by any other procedure.

In conclusion, it should be said that most histologic evidence indicates that the normal vagina is formed from the müllerian ducts and the urogenital sinus. If there is no evidence of müllerian ducts or epithelial buds from them, the new vaginal tract had best be constructed by means of a skin graft, particularly if there has been much difficulty in dissection. In other cases, a graft need not be used.

Seventy-six cases are concerned herein. In each case, reconstruction of the vagina was based on the McIndoe principle. In 70 cases the procedure included use of a Thiersch skin graft; in 6 cases operation was performed without use of a skin graft. The decision as to whether the new vaginal tract should be constructed by the use of a graft must be determined at the time of operation.

ABSTRACT OF DISCUSSION

Dr. F. H. Falls, Chicago: Dr. Counseller is to be congratulated on the large number of patients and the great experience with this operation, which many men with considerable gynecologic experience have never done. I have had no experience with Dr. Counseller's operation, because I have been interested in one which I developed some years ago, which uses the principle of the Pettingill graft. In this operation a circular incision is made in the skin of the perineum at the site of the opening of the normal vagina, often represented by a dimple in the perineum. The edges are deeply undercut, and by blunt dissection between the urethra and rectum a cavity is made and the disk countersunk 3 or 4 cm. Four flaps are made from the edges of the surrounding skin about 1 cm wide and left attached at one end. The opposite end of the flap is sewed to the edges of the countersunk disk. The disk makes the vault of the new vagina and the transplanted flaps serve as four areas from which epithelial cells grow out to line the rest of the vaginal tube. In some cases a sufficiently deep vagina can be produced from one operation; if not, the procedure can be repeated by loosening and undercutting the edges of the new vaginal tube and countersinking it, then turning in flaps from the edge of the vulval opening as in the preceding step. The vagina is packed with iodoform gauze for twenty-four hours and plain gauze thereafter. About four or five weeks should elapse between operations. A vaginal plug is used after epithelialization to maintain distance of the vagina and to deepen it by pressure. The operation should be deferred until shortly before marriage. In 1 case failure to recognize the nature of the deformity led to forceful dilation of the urethra in a teen-aged child, with resultant incontinence of urine. Attempts to reconstruct the vesical sphincter and make an artificial vagina at the same time were unsuccessful. These patients frequently complain of pain occurring about once a month and lasting a few days. On examination and even operation no trace of blood can be found in the abdominal or rudimentary uterine cavities to explain the dysmenorrhea. One patient had a prolapse of the vaginal pouch several months after its construction. We cured this defect by taking strips about 5 cm. long from the inner edges of the rectus fascia which were left attached at the pubis, the free edges united forming a loop which was pushed into the opened end of the vaginal pouch and sutured in this position, thus supporting the pouch from the pubis by ligaments composed of rectus fascia.

Dr. Leo Brady, Baltimore: My experience in making vaginas is limited to 6 cases. In each case an entirely different technic was used, and yet satisfactory results were obtained in all, indicating that, if properly used, there are many different ways in which the vagina can be made. The first patient I operated on in 1935, and she was fortunate in having unusually long labia minora. After dissecting out an opening between the urethra and rectum, I used the split labia minora to cover the raw area, as described by Graves. At that time, Wharton's "vaginoform" had not been described, so I made one of plaster and covered it with a rubber condom. Ten years later she remarried and had no difficulty with sexual relations. She had a vagina 8 cm. long, which easily admitted two fingers, indicating that in the occasional case perhaps use of the dilators is unnecessary. The second patient was a woman whose husband refused to permit any operative procedure. I used Frank's nonoperative method. In six months she was able to make a vagina herself, which turned out to be satisfactory. I feel that only in selected cases will this method be successful. In the third case the findings (and this bears out what Dr. Counseller brought out) were different from the first 2 cases because on rectal examination a large, firm mass could be felt in the midline high up in the vagina. After the dissection had been carried up from below for quite a distance and seemed just about to connect the newly-made vagina with what was thought to be the uterus, I became a little worried and made an abdominal incision. I was surprised to find what had been though to be the uterus was the patient's only kidney. After the abdominal incision had been closed, a Wharton "vagino-form" was successfully used. This case convinced me that intravenous pyelograms should be taken before operation on any woman with a congenital gynecologic abnormality. Dr

The antagonistic tetrad of calcium, sodium, magnesium and potassium is said to control brain irritability, but it is somewhat questionable. Additional research is needed at this point. Magnesium is present in the fetal brain in larger amounts than in any other fetal organ. Why? Potassium apparently influences the permeability and the electrical potential of the cell membranes. The role of potassium in relation to neuron *function seems to be that of modifying the reaction of* the receptor to the transmitting agent (Greville[4] 1940).

Copper and zinc are stored in the brain during intrauterine life and increase slowly after birth. The copper content of the liver and of the basal ganglions is much increased in Wilson's disease.

Selenium and tin are deposited in the gray matter from selenious acid with great specificity, but to a still greater extent in the white matter. This was discovered by treating animals intramuscularly with colloidal selenium. Bismuth and arsenic have practically no selection for brain tissue. Inorganic lead tends to be deposited in bone, but its organic compounds such as tetraethyl lead attack nervous tissues with great avidity. Lead does not become relatively harmless in the brain as in bone. Iron shows great variations in amounts and distribution throughout the nervous system.

There is little storage of mercury in the brain, but it tends to accumulate in the liver and kidneys. Do these heavy metals not reach the nervous system, or does the nervous tissue fail to combine with them? This point requires more elucidation.

The iodine content of nervous tissue bears a close relationship to the thyroxin content. The iodine content *of the tuber cinereum and of the hypothalamic region* increases notably when thyroxin is given orally or intravenously. Bromine seems to parallel the mental state in some respects and is reduced in the blood during stages of excitement. The anterior pituitary contains fifteen to thirty times as much bromine per unit of weight as the other organs of the body. What can the reason be for this phenomenon?

CARBOHYDRATES

Carbohydrates are utilized by the brain as the principal source of energy.[5] The reserve stores are small but those present are very stable. The chief substance is glucose, for which the brain is dependent on the blood stream for its supply. It is contained in the brain tissue in about the same percentage as in the blood. The brain is at the mercy of the pancreas and liver and thus at any time may be on an insecure basis; in contrast it stores lipids and proteins in large amounts and parts with them grudgingly. Curiously and paradoxically the brain of diabetic animals metabolizes carbohydrates.

Glucose taken up from the blood by the brain may be stored as glycogen, or glycolyzed and eliminated from the brain as lactate or oxidized to carbon dioxide.

In each reaction the first step is phosphorylation of *glucose to form glucose phosphate.* One great advance during the past few years has been the clarification of the phosphorylating mechanisms in brain metabolism, and another has been the synthesis of glycogen in vitro.[6]

The main mechanism in breakdown of carbohydrates probably occurs through the oxidation of pyruvic acid, as explained by the Szent-Györgyi-Krebs cycle, and recent work supports the view that vitamin B_1 is concerned in the utilization of pyruvate in the tissues.[7]

The brain is unable to utilize glucose directly, but it must be converted into lactic acid. The brain is a powerful producer of lactic acid, and this substance is vital to carbohydrate metabolism, but no complete Meyerhof cycle has been established. Any animal may die with insulin convulsions with sufficient glycogen in its brain if it were only utilizable.

It is unsafe to apply to the brain criteria gained from carbohydrate metabolism studies on other tissues. Brain tissue forms one of the two exceptions to the rule of "normal adult tissue" as regards glycolysis. Both brain and retina resemble malignant neoplasms in respect to their glycolytic quotients.[3]

Creatine—phosphoric acid or "phosphagen" found in muscle has also been detected in the brain. Additional studies are needed here. In peripheral nerves it may act as one source of energy for the impulse.

As far as the fats are concerned, much of the lipid in the brain belongs to the phosphatide or phospholipid group, that is, the "cephalins," "lecithins" and sphingomyelins. Phosphatides are unique as lipids; they are both water soluble and organo-soluble, they are readily oxidized, they are usually unsaturated, their physical properties are such that criteria of purity are difficult of application and thus their separation is rendered most difficult. The function of the phosphatides in the body is unknown, but possibly it is the transportation of the fatty acids. Both increases and decreases in the phosphatide content of the blood have been found in some of the mental diseases. General paresis and other *demyelinizing diseases show a loss of large quantities* from the brain tissue. Traumatic and hemorrhagic conditions of the brain substance cause a rapid mobilization and depletion of this group of substances.

Deposits of sphingomyelin have been studied in connection with Niemann-Pick's disease in which they are excessively deposited; this in itself is an interesting phenomenon. Although sphingomyelin is found in large quantities in the brain, little of importance is yet known of its function, quantitative distribution or chemical structure.

The recent isolation of new phosphatides, constituting the cephalin fraction, is an outstanding contribution to lipid chemistry; also in 1941 Klenk[8] isolated a new glycolipid with a high sugar fraction from the brain of a patient with amaurotic familial idiocy. It has been obtained from a normal brain, where it constituted 10 to 14 per cent of the total cerebrosides obtained. Sperry and Waelsch (1941)[9] have contributed to the field of lipid synthesis, and Randall (1938)[10] reported on the distribution of lipids in the brain tissue.

Cholesterol is a terpene-like secondary alcohol related chemically to vitamin D, steroid hormones, the bile acids, toad skin poison, carcinogenic substances and a number of other substances. It is present in larger amounts in the brain than elsewhere excepting the adrenal cortex, while the cerebrospinal fluid contains exceptionally small amounts.[11] Adequate methods are now available for quantitative determination. By some workers it has been found to be high in the blood serum of dull, quiet patients with dementia precox and in depressions, while others have reported low values.

The fatty acid esters of cholesterol are found in traces at the most, which is unusual, as all other organs contain some amounts of esterified cholesterol. The body can synthesize and also break down cholesterol. Does the store of sterol in the brain accumulate from local synthesis or is it dependent on blood supply?

Cholesterol is involved in the water metabolism of cells, and the central nervous system is susceptible to changes in hydration. Therefore more data are needed on normal as well as on pathologic relationships.

The precursor of vitamin D has its highest content in fetal brains but is rapidly depleted after birth. This in turn is the regulator of the calcium-phosphorus balance. Ergosterol has been found in the brain of an Egyptian mummy by Kind and his co-workers (1929).[12] On radiation this became active as an antirachitic agent. How can so labile a substance exist so long without decomposition? Vitamin A and its precursor carotene are found in the brain, and defects in these substances cause serious alterations in the functions of the nervous system.

The cerebrosides usually do not appear in the brain previous to medullation. Therefore they are probably insulation substances or possibly are concerned with the nutrition of axis cylinders. They are practically limited to cerebral tissue and only in Gaucher's disease (splenohepatomegaly) do they appear in quantity in other organs of the body.

Neutral fats in the form of glycerides of fatty acids are present in very small amounts if at all in brain tissue, and when found in any quantity indicate a pathologic process.

NITROGEN COMPOUNDS

Gjessing (1939[13] and others have worked on the nitrogen metabolism in periodic catatonia and noted phasic changes.

Nonprotein nitrogen has been measured, but controls have not been efficient enough for reliable interpretation. Ammonia is an interesting substance. Its precursor in the brain may be adenylic acid. It must be determined immediately after removal of the sample as its amount changes rapidly. The specimen is dipped in liquid air, which brings all chemical reactions to a halt. Ammonia may then be determined later. This substance may prove eventually to be very important for understanding brain functions.

Creatine and creatinine are among the best known chemically of the nitrogen substances, but little is known of their function in brain tissue. Very little is known about the kinds of proteins in brain tissue, but most of the amino acids found in other tissues are present. Glutathione is present in rather large quantities in normal brains, but pathologic variations have not been studied adequately.

Little is really known about the composition of the colloids of the brain. Reversibility of at least some of the cerebral proteins can probably occur.

Choline esterase is another interesting substance. Its content in the human fetus increases in parallel with the growth of the neuromuscular apparatus (Youngstrom 1941).[14] The exact role of acetylcholine in relation to nervous activity remains a controversial matter. Some workers believe that it is the specific transmitter concerned with nervous activity at all myoneural junctions and synaptical connections in both central and peripheral parts of the nervous system, while others contend that acetylcholine is little else than a by-product of nerve function or metabolism.

Sympathin is the transmitter substance of the postganglionic sympathetic nerves and is now thought to be identical with epinephrine.[15] The chemical action of epinephrine on plain muscle is still not well understood. Moreover in addition to this action epinephrine also mediates the glycogen decomposition in emotional hyperglycemia.

OTHER PROBLEMS

The effects of oxygen deprivation, respiration of isolated neurons and intermediary oxidation systems, the effects of various narcotics and convulsants, and the acid-base balance phenomena are all large fields now commanding attention and remaining to be completed.

A large number of enzymes have been differentiated in brain tissue, but only a few quantitative estimations have been made. The chemistry in this field is involved, and only in recent years have reliable methods been available.

One enzyme carbonic anhydrase has been studied by Ashby[16] (1947) in its quantitative patterns of distribution. This occurs in the central nervous system, in the hemispheres in approximately one tenth of the level found in the blood. Its potentialities for essential activity are numerous because of its ability to regulate p_H. The stimulus for undertaking this study was the reported mental disturbances following the excessive use of the drug sulfanilamide, which has a considerable degree of specificity for its inhibition.

The patterns of content differ considerably among the higher species of animals and in man, but the particular pattern of distribution of carbonic anhydrase found in man and in the Rhesus monkey has not appeared so far in other animals. Therefore it may possibly be a manifestation of evolutionary development peculiar to the primates.

CONCLUSION

It is the consensus that the various parts of the brain differ from one another morphologically, physiologically and chemically, all of which indicates or at least suggests differences in function. Most of these differences have not been clearly defined. In fact they have not been investigated carefully, as yet. The problem is a complex one and must be divided into many parts for solution.

As Irvine H. Page pointed out in his "Chemistry of the Brain" (1937)[17] no other organ lends itself to study with greater facility than the brain, as blood flowing to and from the brain can be collected and studied and the cerebrospinal fluid constitutes another approach which can be utilized for investigation in health and disease. There are at least six possible technics for studying the chemistry of the brain; namely, (1) the investigation of the substances in the blood which contain or may contain nutritive elements, and products of metabolism, drugs or toxic products of disease; (2) the analyses of cerebral tissue obtained at autopsies, operations and as a part of animal experiments; (3) the analyses of spinal, ventricular and cisternal fluid for metabolic products, drugs and toxins; (4) the analyses of the chemical activity in the special regulating centers for sugar metabolism, respiratory functions and other highly developed nuclei; (5) the study of tissue cultures of selected parts of the brain (the so-called explant technic), and (6) the use of isotopes in brain metabolism.

While considerable knowledge has accumulated on the chemical constitution of the nervous system as a whole, information on its various morphologic elements, on many of its pathologic states, on the chemical changes occurring in the nerve cells and fibers in various physiologic states and into what form of energy it transforms itself in order to become sensation or consciousness or even in actually generating glandular and muscular reactions, is barely outlined.[18]

Many equally important foci and indications for research have not been mentioned in this account, and most of those included are controversial in many details, which serves to reinforce the sole reason for this appeal for more extensive activity in this promising field.

At first glance much of this may seem to be unrelated to the attainment of the desire that we all have of creating and maintaining healthier personalities; i. e., those free from psychoses and overt criminal tendencies. (You will note that I do not include psychoneuroses here. I would leave psychoneurotic persons as they are if they do not suffer too much. Psychoneurotics do most of our creative work—even some of them are research chemists.) But this whole subject is concerned with the very foundations and structure of behavior, both normal and abnormal.

ABSTRACT OF DISCUSSION

Dr. Harold E. Himwich, Fallston, Md.: We have heard a remarkable review of a large amount of material. I will dwell a little on only one point that Dr. Lewis brought forward, namely, the role of acetylcholine. We know that acetylcholine is connected with the function of the peripheral nervous system and is probably secreted at the terminations of the vagus and other visceral nerves and of motor nerves. Atropine diminishes the influence of acetylcholine, and that is why we give atropine to occlude the effects of the vagus on the heart and on the stomach. Similarly, curare is used to overcome the power of motor nerves on muscle. The influence of acetylcholine on the periphery, though not entirely understood, is nevertheless on a satisfactory practical basis. As far as the brain is concerned, our knowledge of the part played by acetylcholine is less satisfactory, yet there are certain indications which are of aid: Physostigmine, which has been shown to increase the acetylcholine content of the brain, brings on nervous symptoms and in excessive doses produces convulsions and even a fatal terminus. Atropine can cut down the effects of acetylcholine on the brain, an action analogous to that in the peripheral nervous system. Dr. Merritt and later Dr. Foster pointed out that convulsions may be associated with faulty acetylcholine metabolism in the brain, and it is worth while to examine their hypothesis. Recent work shows that an increased concentration of cerebral acetylcholine is associated with convulsions of various types; i. e., those produced artificially by electroshock or by pentamethylenetetrazol ("metrazol"). The next step would be to see whether a faulty acetylcholine metabolism is involved in epilepsy and if so what the precipitating cause is of the changes in acetylcholine. Such a point of view presents a new avenue of attack on epilepsy. Just as we have used drugs to increase or decrease the influence of acetylcholine in the peripheral nervous system, we may be able to use them for the same purposes in the brain. When the etiology involves an excess of acetylcholine atropine may be prescribed and for a deficiency of acetylcholine, physostigmine.

Dr. J. M. Nielsen, Los Angeles: I will mention a few little items that have interested me particularly. One is the condition commonly spoken of as progressive spinal muscular atrophy, a generic term for a series of conditions. Some years ago, Dr. Wexler pointed out that some of these conditions were responsive to treatment, and others have proved not responsive. Since then, it has been shown that in certain conditions of hyperthyroidism we get a clinical condition exactly like progressive spinal muscular atrophy, but one which responds to thyroidectomy. There are other conditions in which the muscles suffer, not like progressive spinal muscular atrophy, but much more like dystrophy. Here are chemical differences that we do not understand, apparently of the same origins, but certainly with specific differences. There is another field in which we have a somewhat similar situation. In subacute combined degeneration of the spinal cord, we know that some of those are due to the effects of microcytic anemia, and in those cases, if it is possible to get the blood cell count up to 6,000,000 (it must be distinctly above normal) we can get a recovery, if the degeneration has not been present for a long time. I do not believe that anything that is dead comes back to life, but there are certainly cases of functional paralysis (that not due to destruction of the tracts, but to disease of the tracts which has not become total), in which one can get complete restoration with proper treatment. There are other cases associated, perhaps, with diabetes, other types of anemia, anemia due to Diphyllobothrium latum, bothriocephalus latus, in which we cannot get restoration. Here again, specific chemical differences are present, and it seems to me that there is a broad field in the simple little sphere of tract degenerations of the spinal cord. Some of these, I think, of course affect the cerebral cortex, but it is the same disease, and if one portion of the nervous central system responds, so does the other. Here is one point that we can really work with, with the hope of getting clinical results.

Dr. Nolan D. C. Lewis, New York: I only want to emphasize that I had to make this very sketchy. I couldn't present all of the leads that are included in the paper, but I should like to leave you with a question to think about as to why the chemistry of the brain has been neglected, while so much has been done on the other organs of the body. Particularly as the brain is accessible to so many technics, and is supposed to be the master tissue of the body. Often that "master tissue" is not even removed at autopsy.

Clinical Notes, Suggestions and New Instruments

USE OF ANTIHISTAMINE DRUGS IN THE TREATMENT FOR TRIGEMINAL NEURALGIA

CHARLES E. HORTON, M.D.
and
ANDREW J. BRENNAN, M.D.
Washington, D. C.

Chronic paroxysmal trigeminal neuralgia has been known since early civilization. According to Grinker,[1] it was first adequately described in 1772 by Fothergill. This condition may affect all three divisions of the fifth cranial nerve; it may affect one branch alone, or it may occur in any combination of branches. The first symptom is paroxysmal pain, with gradually decreasing intermissions between attacks. The pain is severe and is described as sharp and shooting, "red hot" or like electric shocks. There may be sympathetic stimulation during the attacks, such as flushing of the affected side of the face, salivation, lacrimation and dilatation of the pupil. The pain usually continues for several hours, and it is characterized by the fact that at any time it may be exacerbated by the stimulation of a "trigger point." Some writers have noted that the paroxysms occur more frequently in spring and fall.

"Benadryl" for intravenous injection, prepared by Parke, Davis & Co., was obtained through Dr. Morris Rosenberg.

This paper is published with the permission of the Chief Medical Director, Department of Medicine and Surgery, Veterans Administration, who assumes no responsibility for the opinions expressed or conclusions drawn by us.

[1] Grinker, R. R.: Neurology, ed. 3, Springfield, Ill., Charles C Thomas, Publisher, 1943, p. 355.

Many methods of treatment have been attempted, but none has been satisfactory. Injections of alcohol[2] around the fifth cranial nerve will control the pain for a few months, but, because of anatomic variations and the necessary trauma[3] associated with the procedure, these injections are not desirable or constantly successful. Many surgical procedures[4] have been attempted, but all are destructive, that is, the sensory nerves, or sometimes, accidentally, both sensory and motor nerves, are severed. This produces organic lesions, paralysis and sensory and trophic changes, which occasionally cause psychic trauma in otherwise healthy persons. It must be emphasized, however, that the pain of trigeminal neuralgia is so severe that such destructive operations are welcomed by the patient who otherwise would be doomed to bear terrifying pain. Indeed, it is thought by many authorities to be the most agonizing pain the human body may endure. Massive doses of thiamine hydrochloride have been used in the treatment for this disease, but with little relief. Only one drug has been used to date with some degree of success. Trichloroethylene, inhaled, may give relief to 1 patient in 6. The drug seems to be specific for the sensory endings of the trigeminal nerve. A careful search of the literature has not revealed a reported case of trigeminal neuralgia in which treatment with antihistamine drugs was successful.[5] A report of a case, in which the pain of trigeminal neuralgia was controlled with antihistaminic therapy, follows.

REPORT OF CASE

G. R. M., aged 48 and a married white housewife, was admitted for the fifth time to the Mount Alto Veterans Administration Hospital, because of repeated attacks of trigeminal neuralgia.

Previous History.—The patient had been having facial pain for approximately sixteen years. Her discomfort began in the left side of the upper jaw and at first was rather mild. She associated this with toothache. For several years she had momentary spasms of pain in the left side of her face, but was not particularly bothered by these mild episodes. About ten years ago these attacks of pain became severer. This caused her to seek medical advice at a large clinic, where on two occasions she received injections of alcohol in the left infraorbital nerve. There was relief for five or six months on each of these occasions. About six years ago she received a similar injection at the Mount Alto Veterans Administration Hospital, with only transient relief. Also about six years ago, she experienced a similar type of pain in the right side of the lower jaw. This rapidly became severer than that on the left side. About three years ago a gasserean neurectomy on the right side was attempted at the Mount Alto Veterans Administration Hospital. Following this operation the patient stated that there was no change at all in the pain on the right side of the face and no alteration in sensation on that side; however, she became deaf in her right ear and tinnitus developed, which has persisted to the present. In view of the absence of sensory changes on the right side, the absence of relief of pain and the deafness, it is believed that the right eighth nerve rather than the fifth was interrupted in the surgical procedure. Approximately two years ago, because of the persistence of severe bilateral pain, she was operated on at the large clinic previously mentioned, where a retrogasserean neurectomy on the left side was performed. Following this procedure there was complete relief of pain on the left side. There has been no recurrence up to the present; in addition, the left side of the face has been numb. A few months after this surgical procedure the pain in the right side of the lower jaw became worse, necessitating hospitalization. The patient was treated symptomatically, and during her hospital stay of one hundred and fourteen days the pain almost completely subsided. In the interval between the periods of hospitalization she took phenobarbital, 0.5 grain (0.03 Gm.) three times a day.

Present Illness.—The patient entered the hospital on July 19, 1947. Since her last discharge from this hospital, Sept. 18, 1946, the pain had been less severe. However, she had always noted that her attacks were mild during the winter. Typical attacks seemed to become severer in the spring season. Further questioning brought out the fact that each year with the ripening of the farm crops her pain was greatly intensified. It was of interest to note that the growing season was delayed approximately one month this year. The exacerbation of her neuralgia was delayed an equal length of time. The pain at the time of last admission was on the right side of the face, involving the lower jaw and the infraorbital region. It had become exaggerated in intensity about three weeks prior to admission. She described two different types of jabbing pain. One of these originated under the right lip and radiated laterally; this was severe but bearable. In the mornings there was in addition severe jabbing pain, which she described as "like two electric wires shocking," which seemed to fan out over the right side of the upper and lower jaws. The pain had been constant. The attacks were precipitated at almost any time by chewing, gentle pressure on the right angle of her lips, brushing her teeth or stroking her right eye. She had not brushed her teeth or chewed her food for the past year and a half. During this time she was accustomed to chopping her food into small particles and placing these in her mouth. She would let her food remain in her mouth a few minutes to moisten it and then would swallow it without chewing.

Physical Examination.—Physical examination at the time of admission revealed that the patient was obviously having severe pain. She moved the right side of her face as little as possible and guarded it constantly. It was noted that the right side of her face was flushed and there was excessive lacrimation from the right eye. The pupils were equal and regular and reacted to light and convergence. Funduscopic examination revealed no abnormality. There was anesthesia and analgesia of the entire trigeminal distribution on the left, and vibration sense was absent over the left maxilla. The corneal reflex of the left eye was absent. There was no objective impairment to any modality of sensation on the right The patient could hear no sound by air conduction on the right, but was able to hear the tuning fork when applied to the mastoid region on the right. There was no definite facial weakness, although the right side of the face was voluntarily moved less than the left. The results of the remainder of the neurologic examination were not remarkable. Her teeth were dirty and carious; the gums were soft and bleeding, and there was pyorrhea. The results of the remainder of the physical examination were essentially negative. Review of her systems was noncontributory.

Family History.—Her family history revealed no evidence of allergic phenomena.

Laboratory Examination.—There were no significant observations in roentgenologic examination of the chest. A differential count disclosed no eosinophils. The urine was normal. Cutaneous sensitivity tests, both scratch and intradermal, yielded negative results except for a slight reaction to the following allergens: rice, chicken, oats, peaches and black pepper.

Course During Hospitalization.—The patient was admitted at 9 p. m., July 19, 1947, with severe pain. She was given 1 grain (0.06 Gm.) of codeine sulfate hypodermically, which treatment was repeated in four hours, without relief. Because of the persistence of pain, 100 mg. of meperidine hydrochloride ("demerol hydrochloride") was given hypodermically every four hours. This medication, also, did not afford relief. Because of the history, and the intensification of attacks with the spring season, the possibility of an allergic basis for the disease in this patient was entertained. Because of this, antihistaminic therapy was begun. The patient was instructed to take 50 mg.

of "pyribenzamine hydrochloride" N.N.R. (*tripelennamine hydrochloride*) initially and a second similar dose thirty minutes later. Within thirty minutes following the first tablet of 50 mg. the previously intractable pain had disappeared completely. The terrifying intensity of her pain is established by a progress note written by the physician on duty the evening of admission and the morning following admission: On July 19 there was a moderate contusion of the dorsum of the right hand at the third metacarpophalangeal joint, sustained in a frenzy of pain. On July 20 the pain seemed intractable; no narcotic seemed to relieve her.

During the next six days the patient was instructed to take 100 mg. of "pyribenzamine" at the beginning of each attack of trigeminal neuralgia. On each of these six days severe attacks were aborted by this treatment. On the seventh day it was decided to give the patient a placebo. The patient thought that she was receiving the medicament that previously had controlled her pain. That evening she experienced a typical attack, which was not relieved by the placebo. The pain continued during the night, over a period of eight hours. However, with the resumption of treatment with "pyribenzamine" the following morning the relief of pain was complete. The patient stated that the "new treatment" had given her the first complete relief of pain since the exacerbation of her symptoms four weeks previously. For two days following the use of the placebo and the readministration of "pyribenzamine," the patient was completely free of pain and required no medication. At this time it was attempted to reproduce the pain by the use of histamine. One tenth of a cubic centimeter of histamine phosphate (1 mg. per cubic centimeter), was injected subcutaneously. In ten minutes a large red raised hard wheal measuring 5 by 11 cm. and with multiple short pseudopodia had developed. Surrounding this was a red area measuring 5 by 11 cm. Also at this time the patient felt the characteristic sharp shooting jabbing pain in her face, although it lasted only a few seconds. No further pain was experienced until six hours later, as she was going to bed. In accordance with instructions, she waited until the pain was well established before taking the prescribed medicament ("benadryl hydrochloride" N.N.R. [diphenhydramine hydrochloride]). Twenty minutes later, after having taken 100 mg. of "benadryl," the pain began to subside, and in thirty minutes the pain had almost completely disappeared. The patient spent a comfortable night and required no more medication.

The following day the patient was free of pain. We decided to make a second attempt to induce an attack by the use of histamine. This time 0.2 mg. of histamine phosphate was injected subcutaneously. In eight minutes a large wheal measuring 2 by 2.3 cm. and with pseudopodia, had appeared at the site of the injection, which was surrounded by a reddened area measuring 7 cm. Approximately ten minutes after the injection was given the patient experienced typical attacks of jabbing pain, which at first were mild but became progressively severer. At this time it was noted that her facial muscles contracted violently with each paroxysm, but these contractions were voluntary, indicating the extreme degree of pain the patient was enduring. She began to cry, and the pain continued unabated, increasing greatly in intensity. During this period of pain, lasting about fifteen minutes, an intravenous infusion of 30 mg. of "benadryl" in 100 cc. of solution of sodium chloride was prepared. This infusion was administered during a five minute period. Two minutes after the infusion was begun the pain began to subside; when about three fourths of the infusion had been given the pain was definitely relieved, and before the entire 100 cc. had been administered the patient was completely free of pain. The total time elapsing from the time that the patient had extreme pain, at which point the infusion was started, to the time when complete relief was obtained was four and one-half minutes.

The following three days the patient had no pain whatsoever and took no medicament of any kind. On the third day following the infusion of "benadryl," a third attempt was made to reproduce the pain with histamine. Again .2 mg. of histamine was given subcutaneously, producing a large wheal similar to the wheal produced in the previous attempts, but no pain occurred. There was a slight flushing of the neck about ten minutes after the injection was given. The patient had a good night's rest, with no recurrence of pain. No medicaments were given. The following day her teeth were cleaned by a dentist for the first time in many years and there was no production of pain, immediate or delayed. Six days after the infusion of "benadryl," on August 6, the patient was given .2 mg. of histamine in 200 cc. of solution of sodium chloride intravenously, over a period of forty-five minutes. Soon after the infusion was started there was flushing of the face and neck; in six minutes there was one tiny jab of trigeminal pain. No further pain was produced. It was suspected that she had been desensitized[6] with histamine, so that no further attempts were made to induce pain for a period of five days. During these five days the patient was released from the hospital and allowed to go home. No medication was given for her use at home. She was able to brush her teeth and carry on a normal life during this period.

After her return to the hospital on August 11, another attempt was made to reproduce the pain, again by intravenous injection of histamine, but the attempt was not successful. However, during the night minimal jabbing pains developed, occuring infrequently, in the right side of the lower jaw. She was given 1/100 grain (0.6 mg) of atropine, with no relief. We decided to attempt to preclude these continual pains completely by the daily administration of "pyribenzamine." On August 12 the patient was given 100 mg. of "pyribenzamine" four times daily. She complained of nervousness and itching and did not sleep well that night. However, the minimal pain which she had been experiencing was relieved. Because of the nervousness and itching, the dose was reduced to 50 mg. four times daily. On the following day there was complete relief of pain with the smaller dose, and there were no reactions noted. She was discharged on the thirty-second hospital day, completely free of pain and with the instructions to take 100 mg. of "pyribenzamine" each time an attack of trigeminal pain occurred.

SUMMARY

A case of typical trigeminal neuralgia is described in which the attacks of pain showed a definite seasonal pattern, being correlated in time with the maturation of spring crops. These attacks of pain were relieved by the administration of "pyribenzamine hydrochloride" N.N.R. (tripelennamine hydrochloride) and "benadryl hydrochloride" N.N.R. (dyphenhydramine hydrochloride).

In pain-free periods typical attacks were provoked by the administration of histamine. After repeated injections of histamine this drug could no longer provoke an attack of trigeminal pain.

Although definite proof is not available the aforementioned observations are consonant with the following theses:

1. The attacks of trigeminal neuralgia in this patient were brought about by the periodic release of some agent resembling histamine, if not histamine itself.
2. The release of the agent was provoked by exposure to some precipitating agent to which the patient was exposed seasonally.
3. The antispasmodic and sedative effect of "pyribenzamine" and "benadryl" were not important in precluding the trigeminal pain, because both atropine and phenobarbital were ineffective; therefore "pyribenzamine" and "benadryl" exerted their therapeutic effect by antihistaminic activity.
4. The ineffectiveness of a provocative dose of histamine, after a series of subcutaneous injections was given, was due to a process of desensitization.

THE STATUS OF PENICILLIN IN THE TREATMENT OF SYPHILIS

(December 1, 1947)

SYPHILIS STUDY SECTION NATIONAL INSTITUTE OF HEALTH
U. S. Public Health Service

Since the report in 1943 by Mahoney, Arnold and Harris,[1] that penicillin was effective in the treatment of early syphilis, at least 500,000 patients with syphilis in its various stages[2] have been treated with this antibiotic.

Even after four years, and despite the large number of patients treated, the available data on the use of penicillin in the treatment of syphilis are provisional in character. Although therapy has not been standardized and routine schedules have not been formally promulgated, penicillin is in fact the principal agent employed today in syphilotherapy in the United States.

The purpose of this report is to summarize for the practicing physician the principal facts of clinical importance with regard to penicillin in syphilis, as compiled by Moore[3] and more recently by the Venereal Disease Division of the U. S. Public Health Service, the Syphilis Study Section of the National Institute of Health[4] and by Arnold, Mahoney, Cutler and Levitan.[5]

THE CHEMISTRY OF PENICILLIN

Knowledge of the chemistry of penicillin is incomplete. However, at least one type, penicillin G (benzyl penicillin), has been synthesized,[6] and at least four other types, F, dihydro-F, X and K, are known to exist.

Most preparations of amorphous penicillin contain mixtures of sodium or calcium salts of two or more types of penicillin. Penicillin G, which is available in crystalline form, is the most effective of the four types studied (G, F, X and K) in the treatment of syphilis in animals and in man.

Penicillin K is the least effective because of its rapid inactivation and anomalous pharmacologic behavior in vivo.

On the basis of presently available knowledge, crystalline penicillin G is the preferred product in the treatment of syphilis of any type in man.

Sodium and calcium salts of penicillin dissolve readily in aqueous, saline or dextrose solutions. Since penicillin in solution loses potency slowly at refrigerator temperature and more rapidly at room temperature, such solutions should not be used after twenty-four hours. Solutions should not be heated.

PHARMACOLOGY OF PENICILLIN

The antibacterial activity of penicillin is determined by microbiologic assay in vitro and is expressed in Oxford, Florey and international units, all of which are virtually equivalent. Dosages of penicillin at present are expressed in terms of units, but ultimately, when chemically pure products are widely available, dosages should and probably will be expressed gravimetrically in milligrams.

Under requirements of the Food and Drug Administration, an ampul of penicillin, whether amorphous or crystalline G, must contain a minimum of 85 per cent of the unitage indicated on the label. Since manufacturers generally include excess unitage to allow for deterioration and to assure meeting minimum requirements, an ampul may contain considerably more units than the label indicates. For this reason most statements in the literature concerning dosages of penicillin in terms of units are approximations.

Penicillin administered in aqueous or saline solution is absorbed and excreted rapidly. It is excreted principally in the urine.

A peak concentration of penicillin in the blood serum is reached promptly on intravenous injection, almost equally rapidly, usually within fifteen minutes or less, following intramuscular injection and more slowly after subcutaneous injection. Concentration of penicillin in the blood serum falls sharply almost immediately after intravenous injection and somewhat less rapidly after intramuscular and subcutaneous administration. Thereafter the drug disappears from the blood at a fairly uniform rate, somewhat more rapidly after intravenous than after intramuscular or subcutaneous injection; and the period of time over which a detectable blood level of the drug is maintained varies primarily with the size of the dose. Penicillin is unequally distributed in the body but appears in most of the tissues and fluids so far studied.

The intravenous single injection method of administering penicillin is of little or no value in the treatment of syphilis because the absorption-excretion cycle is completed too rapidly. Therapeutically effective levels of penicillin in the blood cannot long be maintained with even massive single doses.

Administration of penicillin by continuous intravenous drip has been used by several groups of clinicians, but its practical value in the treatment of syphilis is limited by the necessity for continuous confinement of the patient to bed and the frequent occurrence of thrombophlebitis.

Continuous intramuscular and continuous subcutaneous administration of penicillin have, in addition to the disadvantages of continuous intravenous drip, the further disadvantage of painful local reactions.

The usual method now employed in the administration of penicillin in syphilis is intramuscular injection. Penicillin dissolved in sterile water or isotonic sodium chloride solution, 50,000 to 100,000 units per cubic centimeter, is injected deep into buttock, deltoid or thigh muscles, every two to three hours, day and night, in doses of from 20,000 to 100,000 units.

Subcutaneous injections of similar doses in more dilute solution also have been used, but they are accompanied by painful local reactions.

Although penicillin has been used by the intrathecal route, there is convincing evidence that intraventricular, intracisternal and intraspinal administration is accompanied by risk of dangerous toxic reactions. In view of

In Absorption-Delaying Vehicles (Oil and Wax): The only method of prolonging penicillin blood levels currently suitable in the treatment of syphilis is the use of penicillin in 95.2 per cent peanut oil and 4.8 per cent beeswax. Whether the penicillin suspended in this vehicle is amorphous or crystalline, a single intramuscular injection of 600,000 units (2 cc.) provides a sustained measurable blood level for twenty to twenty-six hours.

The clinical data available as to this suspension are so far based on the amorphous rather than the crystalline product. So administered, however, ten consecutive daily intramuscular injections of 600,000 units each to a total of 6 million units may be expected to provide a failure rate almost exactly comparable (about 15 per cent at the end of one year) to that following the use of 4.8 to 9.6 million units of amorphous penicillin in aqueous solution under hospitalized conditions.

More recently crystalline penicillin G is available as the suspension in oil and wax. If results with this preparation parallel those with crystalline G in aqueous solution, the failure rates will be correspondingly lowered.

A method of penicillin therapy of early syphilis suitable for office use in ambulatory patients is therefore entirely feasible and as satisfactory as the use of aqueous penicillin under hospital conditions. The schedule presently advised is, for crystalline penicillin in oil and wax: total dose, 6 million units; total duration of treatment, ten days; route of administration, intramuscular; individual injection, 600,000 units (2 cc.); interval between injections, twenty-four hours, and total number of injections, ten.

Local discomfort and allergic reactions (such as giant urticaria) are slightly more frequent after penicillin in oil and wax than after aqueous solutions of the antibiotic. Local pain and induration may be minimized, however, by the precaution of clearing the needle, in place in the gluteus muscles, with a bubble of air in order to avoid deposition of the substance along the needle track in subcutaneous fat.

Penicillin Administered Concurrently with Other Treatment Methods.—Experimental evidence indicates an advantage if penicillin is given simultaneously with arsenic or a bismuth compound or during artificial fever. In man, however, the benefits of such combined treatment are not definite, at least in the dosages and over the periods so far studied. The addition of a maximum of 480 mg. of oxophenarsine hydrochloride (eight injections of 60 mg. each, given daily or every other day) and/or of 1,000 mg. bismuth subsalicylate (five injections of 0.2 Gm. each given every two to three days) to concurrent penicillin therapy has not greatly reduced the failure rates; nor has it been possible to improve results by penicillin administered during adjuvant fever therapy. Moreover, the addition of these adjuvants changes a practically innocuous method of treatment into a more dangerous one.

For these reasons, and since the results from penicillin alone seem so satisfactory in early syphilis, adjuvant therapy with arsenic, bismuth preparations, or fever is not advised as a first course of treatment.

However, there are some theoretic and perhaps practical advantages to a combined therapeutic attack in patients who have failed after an original course of penicillin.

Retreatment of Penicillin Failures.—Retreatment must, of course, be given to those patients who have clinical relapse (including reinfection) or serologic relapse and probably should be given to those patients who still show significant seropositivity (4 dilution or 16 Kahn units) a year after the original course. In these circumstances and in view of the fact that retreatment with penicillin alone is followed by a higher failure rate than is original treatment, consideration should be given to the use of a retreatment course consisting of crystalline penicillin G (administered either in aqueous solution or in oil and wax as already mentioned) and in addition, simultaneously with and after the penicillin course, 600 mg. oxophenarsine hydrochloride given every other day in ten intravenous injections of 60 mg. each over a total of nineteen days and 2,000 mg. bismuth subsalicylate in oil given every five to seven days in ten intramuscular injections of 200 mg. each (of the salicylate, not of bismuth metal) over a total period of fifty to seventy days.

It must be recognized that arsenic and bismuth in these dosages increase the risk of serious reactions or death from treatment. The anticipated mortality rate is about 1 in 30,000.

LATENT SYPHILIS

The use of penicillin in the treatment of latent syphilis, in which the only evidence of the disease is the positive serologic test, is based on the assumption that since the drug is effective in the treatment of early and late syphilis, it may be expected in latent syphilis to prevent development of clinical manifestations of the disease. On this assumption, many clinicians are treating latent syphilis with the same schedules of penicillin therapy used in the treatment of early syphilis.

Penicillin is no more effective than arsenic and bismuth in reducing the quantitative titer of the serologic test for syphilis. The significance of this observation, however, must be interpreted in light of the facts that reversal to serologic negativity is not a necessary criterion of success in the treatment of latent syphilis and that, irrespective of method or duration of treatment, seroresistance is the rule in syphilis of more than five years' duration.

A post-treatment observation period of ten to twenty-five years will be necessary to determine whether penicillin offers the patient the 95 to 98 per cent chance of future clinical health which is offered by six months of arsenic and bismuth therapy. Despite the lack of assurance of clinical success, penicillin treatment of latent syphilis offers the advantages of brevity, safety and freedom from risk of reaction from heavy metals. If it is used, periodic post-treatment laboratory and clinical examinations are especially important.

For patients with seroresistant latent syphilis who previously have received six months of continuous metal chemotherapy or its equivalent, the use of penicillin produces no presently apparent clinical or serologic results other than an occasional gain in weight.

BENIGN LATE SYPHILIS

Early clinical results indicate that total dosage of 2 to 4.8 or more million units of penicillin is effective in healing cutaneous, mucocutaneous, osseous and hepatic lesions of benign late gummatous syphilis. Although many years of observation will be required to determine the ultimate clinical outcome of this type of syphilis treated with penicillin, the immediate results appear to be as good as those of arsenic and bismuth therapy.

CARDIOVASCULAR SYPHILIS

The value of penicillin in the treatment of cardiovascular syphilis cannot be determined until there has accumulated a large series of post-treatment observations comparing the life expectancy of patients treated with penicillin with that of patients treated with other drugs or not at all. The available evidence indicates that the Herxheimer reaction (therapeutic shock) cannot be avoided, at least in early syphilis, by initiating penicillin treatment in extremely small doses. Since this may also be true in cardiovascular syphilis, and since therapeutic shock in such patients may have disastrous results, it is suggested that in syphilitic aortitis with aortic regurgitation, saccular aneurysm or obvious or masked coronary or myocardial disease it may be advisable to withhold penicillin altogether, or at least until after preparatory treatment with heavy metals has been given. If penicillin is used, the total dosage should be large (5 or more million units), the individual doses relatively small (25,000 to 40,000 units) and the duration of treatment prolonged (fifteen or more days).

OCULAR SYPHILIS

Syphilitic Iritis.—Penicillin is safe and rapidly effective in the treatment of syphilitic iritis. The time and dosage schedules of treatment are similar to those employed for early syphilis in general.

Interstitial Keratitis.—In the treatment of interstitial keratitis penicillin is of uncertain value, even when a total dose of 4 to 10 million units is employed. Less than half the patients respond promptly. Penicillin administered locally at least three times daily by iontophoresis, penicillin-soaked cotton packs or in ophthalmic ointments has appeared to be effective in a small number of cases. Fever induced by tertian malaria, typhoid vaccine or other means, combined with arsenic and bismuth therapy, should be used if acute inflammation and corneal infiltration do not respond promptly to penicillin therapy.

Syphilitic Primary Optic Atrophy.—The effectiveness of penicillin in primary optic atrophy will require years of observation for determination. Meanwhile, and because of its established value in arresting the progress of primary optic atrophy, induced malaria should be used along with penicillin therapy.

THE PREVENTION OF PRENATAL SYPHILIS

Penicillin is nearly 100 per cent effective in the prevention of prenatal syphilis. It is preferable to conventional arsenic and bismuth therapy, which under these circumstances is unnecessary and undesirable. In maternal early syphilis penicillin is equally effective in protecting the fetus regardless of the trimester of pregnancy in which treatment is given (certainly up to the eighth month of pregnancy). In any stage of the maternal infection, penicillin should be used as soon as the diagnoses of syphilis and pregnancy have been established. The available evidence indicates that penicillin in ιqueous solution is probably superior to the suspension n oil and wax in this special circumstance. Schedules 'hich have been used successfully for pregnant women have provided total doses of 4.8 to 6 million units of penicillin in aqueous solution administered at two to three hour intervals over periods of eight to fifteen days.

Following completion of penicillin treatment, the mother must be followed clinically and with quantitatively titered serologic tests, at least as often as once a month until delivery. After delivery, follow-up examinations should be based on the stage of the mother's infection.

Retreatment with penicillin should be given to the mother during pregnancy if (*a*) there is evidence of clinical or serologic relapse, or (*b*) the mother has previously untreated or inadequately treated syphilis of less than four years' duration and the original maternal serologic titer does not significantly decline within three months after treatment.

The infant must be followed after birth for a minimum period of four months, by means of (*a*) frequently repeated physical inspections, (*b*) quantitatively titered blood serologic tests, preferably every two weeks [10] and (*c*) roentgenograms of the long bones taken preferably at the first and sixth weeks of life.

CONGENITAL SYPHILIS

Infantile Congenital Syphilis.—Penicillin in aqueous solution, administered every two or three hours day and night in a total dosage of 100,000 to 400,000 units per kilogram of body weight over a period of eight to fifteen days, is a more satisfactory method of treating infantile congenital syphilis (in children up to 2 years of age) than any schedule yet employed. The effect of penicillin in oil and wax has not yet been thoroughly studied in infants and young children.

The death rate among syphilitic infants treated with penicillin appears to be no greater than among those receiving conventional heavy metal therapy. Most of the deaths are attributable to causes other than syphilis, which is a contributory factor in only a minority. Many of the difficulties encountered in the management of syphilitic infants are due to infectious or nutritional causes other than syphilis, and good pediatric care is essential.

Late Congenital Syphilis.—Results of treatment of patients manifesting the various forms of late congenital syphilis have been essentially similar to those of patients with analogous manifestations of the acquired disease. Whether penicillin will permanently arrest the progression of late or latent congenital syphilitic infection cannot be ascertained for many years.

NEUROSYPHILIS

Asymptomatic Neurosyphilis.—Penicillin exerts a profoundly favorable effect on the spinal fluid abnormalities in early and late asymptomatic neurosyphilis. Most striking and prompt is the reduction of the cell count during treatment, with its usual return to normal by ten to twenty-four weeks after treatment. In most cases the cell counts have remained normal throughout continued post-treatment observation. The protein content is also reduced promptly but less strikingly. Normal values are usually reached by the sixth month and maintained thereafter. The Wassermann complement fixation reaction and colloidal tests improve more slowly.

---

[10] Normal infants born of seropositive mothers may themselves be seropositive at birth and for a few weeks thereafter due to the placental transfer of maternal reagin. Infants should not be treated for syphilis on serologic grounds alone, unless the serologic titer is sustained or rising in successive tests at four to eight weeks after birth.

In each of these tests the trend toward normal is dependent on the degree of the abnormalities before treatment and the duration of infection, with response more prompt and satisfactory in early than in late asymptomatic neurosyphilis.

The effect of penicillin on the quantitative blood serologic titer in both early and late asymptomatic neurosyphilis is similar to that of arsenic and bismuth treatment.

Symptomatic Neurosyphilis.—Penicillin administered intramuscularly beneficially influences all spinal fluid abnormalities in symptomatic neurosyphilis of any type fully as promptly as in asymptomatic neurosyphilis. There is some evidence that penicillin plus malaria has an even more favorable effect on the spinal fluid.

The influence of penicillin on the multiplicity of clinical manifestations of symptomatic neurosyphilis is not so readily assessed, principally because of the difficulty of distinguishing between clearcut clinical improvement in symptoms due to the inflammatory component and those dependent on irreversible degenerative changes in tissue. In general it may be said that symptomatic responses are better than those obtained by metal chemotherapy. An exact comparison of penicillin with fever therapy is not yet possible.

Acute Syphilitic Meningitis.—Penicillin in a total dose f 5 to 10 million units has resulted in immediate ymptomatic improvement with disappearance of headache and stiff neck within two days, disappearance of cranial nerve paralysis in most cases, gradual improvement of nerve deafness and the relief of convulsions. In most such cases the blood serologic titer and the spinal fluid have reverted to complete normality and have remained so.

Dementia Paralytica.—Penicillin alone in paresis and taboparesis has now been used long enough to show that it extends the average four year life expectancy of the untreated patient.

Observation of clinical effects on patients treated with penicillin show moderate to definite improvement in the mental status of about half the cases, no improvement or further deterioration in 20 to 40 per cent. and death in 6 to 10 per cent up to two years after completion of treatment Many paretic patients whose mental condition prevented employment before treatment have been able to return to work.

Frequent and striking improvement in such symptoms as tremor, defects in writing and speech, undernutrition, and brain wave abnormalities shown by the electroencephalogram has been observed among penicillin-treated persons with paresis.

There is some evidence which indicates that the transformation of the psychosis to manic, schizoid or paranoid trends in patients in whom these manifestations previously were absent may occur more frequently after penicillin therapy than after fever therapy. There is also a possibility that complete restoration of preparetic mental status may be less frequent after penicillin alone than after treatment with fever.

There is some evidence, not yet conclusive, that penicillin plus malaria may give better clinical results in the treatment of paresis and taboparesis than are given by penicillin alone.

Tabes Dorsalis and Taboparesis.—Because of the erratic and unpredictable course of untreated tabes dorsalis, in which spontaneous remission or arrest is known to occur, it is difficult to determine the real influence of penicillin in this disease. Data are not yet available to determine whether penicillin therapy will arrest permanently the tabetic degenerative processes. Penicillin has varying effects on the different symptoms characteristic of tabes dorsalis and taboparesis. Decrease in frequency and severity of lancinating pains has been reported by about half the patients, but in some this improvement has not been maintained. Some degree of improvement has been observed in subjective paresthesias. A few patients have reported complete relief from gastric crises. About half those with tabetic ataxia have shown improvement in gait, but some of this may have been coincidental. Improvement, sometimes striking, in urinary disturbances has occurred. In the majority of tabetic males among whom impotence was a symptom there is no improvement, and in none has there been a complete return to normal. Charcot joints and trophic ulcers have not been influenced favorably. Meager available data suggest that penicillin in combination with malaria may be more effective in treatment of tabes dorsalis than penicillin alone. Penicillin appears to be more effective than arsenic and bismuth compounds and is to be preferred because of lower toxicity.

Diffuse Meningovascular Neurosyphilis. — Clinical improvement after treatment with penicillin among patients in this diagnostic category, excepting Erb's paraplegia and nerve deafness, has been approximately the same as that observed after arsenotherapy.

Syphilitic Epilepsy.—Information on the few neurosyphilitic patients with epileptiform seizures who have been treated with penicillin alone indicates that convulsions are not prevented and that anticonvulsant medication is necessary.

Erb's Syphilitic Spinal Spastic Paraplegia.—No clinical improvement and virtually no improvement in spinal fluid abnormalities. have been observed in the few patients who have been treated with penicillin for Erb's syphilitic spinal spastic paraplegia. Penicillin apparently is similar in this regard to other methods of treatment.

Syphilitic Nerve Deafness.—Return to normal hearing, or great improvement in hearing, has been achieved by penicillin therapy in patients suffering with syphilitic nerve deafness accompanying acute syphilitic meningitis. Improvement in the hearing of about half the patients treated with penicillin for late syphilitic nerve deafness has been effected, and arrest of progression of impairment of hearing has been achieved in others.

Penicillin Alone Versus Penicillin Plus Fever.—A total of 4 to 10 million units of penicillin alone in aqueous solution administered over a period of seven and one half to twenty-one days, is suitable for the initial course of treatment for patients with early or late asymptomatic neurosyphilis, acute syphilitic meningitis, diffuse meningovascular neurosyphilis, gumma of the brain or cord and vascular neurosyphilis.

A total of 10 to 20 million units of penicillin administered over a period of twelve to twenty days accompanying induced malaria fever is advisable, unless the latter is contraindicated, for patients with neurosyphilis entailing a serious threat to life or vital functions, e. g., dementia paralytica, taboparesis, primary optic atrophy, nerve deafness in late syphilis, nonparetic syphilitic epilepsy and Erb's spinal spastic paraplegia.

Data are not yet available permitting a comparison of penicillin in aqueous solution with penicillin in oil and wax in neurosyphilis.

POST-TREATMENT OBSERVATION

Careful post-treatment observation over an indefinite period of time is essential for syphilitic patients treated with penicillin. Many years must pass before the probable ultimate outcome of penicillin therapy for syphilis can be definitely stated. Each patient should be educated by the physician or clinic as to the importance of continuity of his own post-treatment follow-up.

Early Syphilis.—During the first year after treatment, the patient should return once a month for (*a*) inspection of the skin and mucosae (patient completely stripped —especial attention to buccal cavity and anogenital region) and (*b*) blood serologic tests for syphilis quantitatively titered.

Relapse, clinical or serologic, is most likely between the fourth and ninth months after treatment and should be especially watched for at this time. Clinical relapse (of the infectious mucocutaneous variety) is usually preceded by serologic relapse.

Serologic relapse may be represented either by a return of positivity in a serologic test for syphilis which has already reversed to negative or by a sustained increase in titer in one which is still positive.

Seroresistance may be apparent almost from the start of treatment, in that the titer of the serologic test remains at pretreatment level or falls only slightly; or it may not be obvious for twelve to twenty-four months (a titer which falls slowly during this period of time and then stabilizes at a low level).

Retreatment during the first year is indicated for: (*a*) clinical relapse of any type (infectious mucocutaneous, ocular, supposed reinfection or neurorecurrence; (*b*) serologic relapse (confirmed by two or three repetitions of the serologic tests in order to exclude laboratory variations); (*c*) abnormalities in the spinal fluid (asymptomatic neurosyphilis) if present six months or later after treatment; (*d*) the birth of a syphilitic infant, and/or (*e*) failure of the blood serologic titer to fall appreciably within the first six months after original treatment. Retreatment need not be given if seropositivity persists at a low titer (fluctuating) or if the trend toward seroreversal is still downward.

The spinal fluid must be routinely examined at about the sixth month. If it is normal and if progress has been otherwise uneventful (persistent seronegativity of the blood, no evidence of clinical progression or relapse), the spinal fluid examination should be repeated two years after treatment. If it is then negative and if uneventful progress continues, this examination need not be repeated.

During the second year after treatment, assuming that progress has been so far satisfactory, the blood serologic test for syphilis may be done every three months, rather than monthly.

During the third and subsequent years, for an indefinite period of time, the tests should be done every six months. Annual physical examinations should be performed, with special reference to ocular fundus, neurologic and cardiologic status.

Infantile Congenital Syphilis.—Infants treated with penicillin should be followed exactly in the same manner as adults with early acquired syphilis.

Pregnant Women with Syphilis.—If the mother's infection is recent (manifest early syphilis during pregnancy, early latent syphilis of less than four years' duration), she should be followed during and after delivery in the same manner as patients with early acquired syphilis.

For maximum protection of the infant, such mothers should be retreated during pregnancy not only for obvious clinical or serologic relapse but also for an unchanged or persistently high serologic titer.

If the mother's infection is latent and of longer standing than four years, such frequent follow-up is not essential and retreatment is not necessary because of failure of serologic response. Seroresistance after penicillin is the rule in late latent syphilis, as it is after all other forms of treatment.

Infants Born of Syphilitic Mothers.—Infants born of mothers who had primary or secondary syphilis during pregnancy should have a serologic test for syphilis done at birth (cord or venous blood), every two weeks thereafter for the first two months and again at the third and fourth months of life. Infants born of mothers with latent syphilis should have a serologic test done at birth (cord or venous blood), at six weeks and again at the third and fourth months.

About 20 per cent of normal nonsyphilitic infants born of treated but still seropositive mothers are themselves seropositive at birth. A positive serologic test in the infant at this time (or within the first month of life) is not an indication for immediate treatment of the child unless confirmed by other evidence of congenital syphilis (clinical or roentgenologic). Serial quantitative titration of the serologic test in seropositive infants is essential.

Routine roentgenograms of the long bones should be taken one week and six weeks after birth.

If the infant is seronegative and otherwise normal at 4 months of age, it may be dismissed as nonsyphilitic.

Late Syphilis (Excluding Neurosyphilis).—For any type of late syphilis, whether latent or with lesions (excepting neurosyphilis), the patient should have, as a minimum, quantitatively titered serologic tests every six months and periodic annual physical surveys for the duration of life.

Neurosyphilis.—In neurosyphilis of any type, the spinal fluid should be retested every six months for the first two to three years and at yearly intervals thereafter. The most important of several tests of the spinal fluid are the two which are too often omitted: cell count and quantitative estimation of protein. If these two fall to normal and remain so, regardless of the response of the spinal fluid Wassermann or colloidal curve, the process in the nervous system is probably inactive and clinical relapse or progression is unlikely. Conversely, if cell count and/or protein content remain elevated with no trend toward normal, or if after becoming normal either or both increase to abnormal levels, a recrudescence of activity is probable and treatment in some form (preferably with fever and penicillin) should be repeated.

In addition, periodic neuropsychiatric reexamination (with special examinations as indicated, e.g., ocular fundi, visual acuity, visual fields in primary optic atrophy and audiometer tests in nerve deafness) should be repeated at least as often as every six months for the first two to three years and yearly thereafter.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

535 North Dearborn Street - - Chicago 10, Ill.

Cable Address . . . . "Medic, Chicago"

Subscription price . . . . . Twelve dollars per annum in advance

Please send in promptly notice of change of address, giving both old and new; always state whether the change is temporary or permanent. Such notice should mention all journals received from this office. Important information regarding contributions will be found on second advertising page following reading matter.

SATURDAY, MARCH 27, 1948

EDITORIAL ANNOUNCEMENT

The absence of the compositors employed by the American Medical Association from their work continues. This issue of THE JOURNAL has been prepared largely by the use of Vari-Typer machines Because of the difficulties of reorganization of the headquarters office necessitated by this situation, the editorial material in this issue of THE JOURNAL has been greatly condensed.

AMERICAN CANCER SOCIETY CAMPAIGN

Typical of the American way in meeting the challenge of our major problems in disease is the work of the American Cancer Society, representing the biggest type of cooperation between a voluntary organization, the medical profession and the public. The confidence of the people of the United States in this organization is indicated by the recent increase in the funds made available to the American Cancer Society by voluntary subscriptions. The total annual income has gradually increased from a few hundred thousand dollars a year to a goal in 1948 of $15,000,000.

In the development of its services the medical and scientific department of the American Cancer Society has created four divisions, including a library, a division of statistical studies, a division of service and a division of professional education. The library is being developed as the most complete repository of information on cancer that can be assembled. Each month a bibliography of current literature on cancer is made available to the medical profession. Reprints are being collected for a library service covering every aspect of the cancer problem. In the attack on cancer accurate statistics are necessary, and the division of statistics is now collecting, collating and disseminating all the available information concerning the incidence of cancer and its mortality in relationship to many conditions likely to affect these figures.

Prominent in the developments of the American Cancer Society is the creation of "cancer detection centers." Thus far the statistics division has collected data on forty-three centers, and the information derived from this study will guide the future development of similar centers in the United States. The statistics division also aids in the development of records for recording cancer.

Recent studies show that there are now three hundred and twenty-four cancer information services in the United States and a total of one hundred and fifty cancer detection centers which meet the standards established for such centers by the American College of Surgeons. In addition, there are thirty-five other centers designed simply to examine apparently well persons for cancer. Investigations indicate also that there are now four hundred and seven clinics in the United States which specialize in the diagnosis and treatment of cancer. The estimates show that a clinic may serve effectively a population of 100,000; around nine hundred additional cancer clinics are needed. Many of the branches of the American Cancer Society are carrying on special services for advanced cases of cancer with terminal illness. Prominent also among the functions of the service division is the work of the field army, which aids with the making of dressings, transportation of the sick, help in supplying equipment for the sick room and personal comforts to patients with cancer.

Another aspect of the work of the American Cancer Society is the education of physicians. Studies are being made of the extent to which cancer is being taught in our medical schools. Panels are being created for graduate education of physicians throughout the country. Nineteen states have established speakers bureaus and four more are in process of formation. The American Cancer Society is developing selections of lantern slides, motion picture films and similar educational material which are available to those lecturing in the field. Plans have been made for the making of seven motion pictures in color. A motion picture library covering all existing films on cancer is being established, and thirty-nine available films are now being duplicated. The American Cancer Society has cooperated with the American Medical Association in publishing sixteen articles in THE JOURNAL. Contemplated also are a series of monographs and the establishment of a new journal for the practicing medical profession to be called *Cancer*.

Recently the American Cancer Society has approved the establishment of twenty annual fellowships in the care of patients with cancer to be awarded to young physicians who desire to obtain advanced training in the diagnosis and treatment of this disease. Fellowships have also been established for the study of statistical analysis. Among recent activities have been the development of a conference on cytologic diagnostic methods in Boston, April 12 and 13, and a grant to the American Radium Society to support a conference on breast cancer at its forthcoming fifthieth anniversary meeting.

This intensification of activities directed against this most feared of all diseases will yield in the near future a positive control beyond anything available anywhere else in the world. The pattern in the securing of funds and in the organization of activities follows the leadership of the National Foundation for Infantile Paralysis, which is being followed also with some modifications by the American Heart Association. Surely here again is proof of the outstanding merit of the voluntary American way of life in the attack on disease.

Current Comment

ARCHIVES OF SURGERY

Twenty-eight years ago a group of American surgeons requested the American Medical Association to publish a periodical dealing with clinical and experimental investigations in the field of surgery. The editors of the *Archives of Surgery* have decided now to establish new sections in the *Archives* which should make it appeal to a still larger number of surgeons in this country. The *Archives of Surgery* will introduce a new section called "The Surgical Forum," to be conducted by Dr. Robert Elman of the editorial board. In this section will be published queries and answers in regard to surgical problems, unusual surgical experiences and subjects for discussion about which the readers desire additional information. Arrangements have been made whereby the papers presented before the Western Surgical Association and the Central Surgical Association will be published in the *Archives*. A third new feature will be "The Surgical Clinic", in which section will be published at appropriate intervals the verbatim report of the discussion of a case as conducted by members of some surgical staff, in addition to the history, physical findings, laboratory and roentgen ray. The Surgical Clinic section will be supervised by Dr. Gustaf E. Lindskog, of the editorial board.

CORNELIAN CORNER

Cornelia, daughter of Scipio Africanus the Elder and mother of the Gracchi, following the death of her husband refused numerous offers of marriage and devoted herself instead to the education of her twelve children. When asked to show her jewels, she presented her sons, saying, ''These are my jewels.'' Her name is recorded in history as that of a mother devoted to her children. Now it is further perpetuated by an organization established in Detroit in 1942 called the Cornelian Corner. When the kitchen used to serve the whole family as a living room, the mother would face a corner of the room when nursing her baby. This custom is commemorated in the second half of the name of this extraordinary organization. The increase in our knowledge of psychosomatic medicine has emphasized the importance of early impressions on the growing infant. Specialists in the fields of pediatrics, obstetrics, psychiatry and child development and others interested in restoring the close relationship that used to exist between the mother and the growing child are members of the group. Among other activities, breast feeding is emphasized as a necessary concomitant to proper rearing. Many of our current practices tend toward spartan routine rather than loving care. The importance of emotional security for the baby is now recognized. As Dr. Leo H. Bartemeier[1] points out. the program of the Cornelian Corner "aims at relief of the cultural tensions so incident to feeding, toilet training and child discipline." Among other planks in the program are abandonment of the artificial practice of separating the newborn child from its parents, encouragement of the breast feeding of infants with opportunity to nurse whenever they are hungry or anxious, and postponement of the establishment of sphincter control until the baby can walk, verbalize its needs and learn to be clean and dry through imitation, curiosity and familiarity with the toilet. These are radical departures from previous methods of infant care. The professional experience of recent years, supplemented by the fundamental research of Aldrich and his group, seems to indicate that the proponents of the Cornelian Corner have begun a new epoch in infant care.

---

ORGANIZATION SECTION

Official Notes

Following is the list of stations broadcasting the program, as reported by the National Broadcasting Company:

N.B.C. BROADCAST SCHEDULE

"Doctors Today," which is broadcast over approximately one hundred and forty stations of the N.B.C. Network coast to coast offers the following topics in the weeks to come:

March 27	Allergy.
April 3	Cancer in Children.
April 10	Public Health Nursing.
April 17	The Public Wants a Doctor;
May 1	Child Guidance.
May 8	Human Brucellosis.

These programs are supervised by Judith C. Waller and written by William J. Murphy of the Central Division, National Broadcasting Company, Chicago, and produced by Norman Felton. The twenty piece orchestra of the National Broadcasting Company is directed by Bernard Berquist. Scientific supervision is by Dr. W. W. Bauer, director, Bureau of Health Education.

In some instances the time of the network program conflicts with local commitments. In these instances recordings of the program are made and broadcast at a subsequent hour. Local radio columns should be consulted. The program goes on the network at 4 p.m. Eastern standard time, 3 p.m. Central standard time, 2 p.m. Mountain standard time and 1 p.m. Pacific standard time.

Transcriptions on Physical Medicine Available

The Bureau of Health Education in cooperation with the Council on Physical Medicine announces the distribution, beginning March 15, of electrical transcriptions devoted to phases of physical medcine. The recordings each last fourteen minutes and thirty' seconds. The topics and speakers are as follows:

1. Infantile Paralysis—Dr. Robert L. Bennett, Warm Springs, Ga.
2. Massage—Dr Morris A. Bowie, Bryn Mawr, Pa., and Dr. George M. Piersol, Philadelphia.
3. Exercise—Dr. Frank H. Ewerhardt and Fred V. Hein, Ph.D., Chicago.
4. Local Applications of Heat and Diathermy—Dr. Frank H. Krusen, Rochester, Minn.
5. Sunlight, Real and Artificial—William W. Coblentz, Ph.D., Washington, D. C.
6. Hearing Aids—Dr. Hallowell Davis, Boston.
7. Radioactive Substances—Dr Hymer H L Friedell, Cleveland.
8. In Bed or out—Dr John H. Powers, Cooperstown, N. Y.
9. Occupational Therapy—Dr. Winfred Overholster, Washington, D. C.
10. Oxygen in Medicine—Dr Ralph M Waters, Madison, Wis.
11. Shoes and Artificial Limbs—Dr Frank R Ober, Boston.
12. Physical Treatment in Psychiatry—Dr. Arthur L. Watkins, Boston.
13. Skin, Hair and Electrolysis—Dr. Anthony C. Cipollaro, New York.

The series as a whole is loaned without cost, except that borrowers are requested to pay the return transportation, to local medical societies or for use in broadcasting projects approved by such societies. No authorization will be given to broadcast individual selected records from this series. Local groups that borrow the transcriptions are expected to make all local arrangements for radio time and for publicity and are likewise expected to take the responsibility for prompt return of the records after their use. For information address the Bureau of Health Education and ask for the Radio Handbook and the transcription listings, single copies free.

Washington Letter

(From a Special Correspondent)

March 25, 1948

Disabling Work Injuries

The Bureau of Labor Statistics reports that for the seventh consecutive year disabling work injuries affected more than 2,000,000 persons during 1947. Rising employment and the effects of two major disasters were blamed for offsetting some improvement in the general aspects of on the job safety. The 1947 total of such injuries was reported at 2,059,000, a rise of 1 per cent above 1946. About 17,000 persons were killed in accidents, on the job, as compared with only 16,500 in 1946, a 3 per cent increase. This increase was traced primarily to the Texas City explosion and the Centralia, Ill., mine disaster.

Senator Taft Opposes Free Medical Or Dental Care

In a statement read at the five day postgraduate clinic of the District of Columbia Dental Society, Senator Robert A. Taft, Ohio, stated that "I feel very strongly that the federal government should not encourage any general program of free medical or free dental care for everybody." Senator Taft is author of the health bill introduced in opposition to the administration-supported national health insurance plan.

Plans For National Health Assembly Being Formulated

Federal Security Administrator Oscar R. Ewing announced that plans for the National Health Assembly, to be held here May 1 to 4 were discussed at a meeting of the executive committee. The assembly is to be held to guide the federal agency in drawing up a ten year health program for the nation at the request of President Truman.

Young Americans Crippled by Poliomyelitis

A Metropolitan Life Insurance Company survey reveals that nearly 74,000 Americans under 21 years of age were crippled because of poliomyelitis, as of one year ago. The total had increased about 10 per cent in the past two years and almost 45 per cent in the past seven years.

Second Major Cancer Research Award Announced

A $50,000 gift to Georgetown University was received from Mrs. Mabel C. Hinshaw in memory of the Metropolitan Opera baritone, William Wade Hinshaw, which will be used in an intensive cancer research project at the new Georgetown Hospital, officials announced. The American Cancer Society recently awarded $60,000 to the Warwick Clinic, affiliated with George Washington University, for cancer research.

Medical Legislation

STATE LEGISLATION

California

Bill Introduced.—A Constitutional Amendment proposes an amendment to the state constitution which would authorize and direct the legislature to establish a system of health and hospital insurance for the people of the state. The proposed amendment would require the inclusion in such program of dental care and routine periodic physical checkups.

New Jersey

Bill Passed.--A. J. Res. 2 passed the senate March 15. It proposes the creation of a commission to make a survey of all voluntary charitable hospitals throughout the state to determine what steps can be taken to relieve existing overcrowding and to furnish additional revenue for operating costs to relieve the burden now being carried by the voluntary charitable hospitals.

New York

Bills Introduced.--A. 2704 proposes the enactment of an amendment to the public health law providing for the organization and operation of a comprehensive statewide system of health insurance. A. 2870 proposes the creation of a state commission to make a study and survey of the prevalence and facilities for the treatment of all forms of heart disease. A. 2878 proposes to make it a misdemeanor for any person to diagnose or treat human ailments by use of hypnotism without first being licensed to practice medicine within the state. A. 2964, to amend the public health law, proposes certain regulations relating to the emergency care and treatment of persons suffering from tuberculosis.

Bills Passed.--A. 2416 passed the assembly March 9. To amend the public health law, it proposes to make it the duty of every physician to give notice to the health officer of his respective county, city town or village of every case of cerebral palsy under his care. A. 2479 passed the senate March 8. To amend the public health law, it proposes to amend the law relating to persons, firms and corporations procuring blood donors so as to eliminate the existing requirement that donors present a satisfactory physical examination showing freedom from communicable disease. The proposal requires instead that the donor comply with the requirements of the state sanitary code or, in New York City, with the city sanitary code. S. 2467 passed the assembly March 10. To amend the education law, it proposes that after July 1, 1949 medical students performing clinical clerkships or similar functions in a legally incorporated hospital shall be exempt from the provisions of the medical practice act

South Carolina

Bills Introduced.--S. 1280, to amend the hospital licensing law, proposes to designate the state board of health as the sole agency for control of and participation in the program for the construction, repair, location and other activities necessary to be carried out in the so-called hospital construction act.

Bills Passed.--H. 1214 passed the house March 10. It proposes to put sulfanilimide, sulfathiazole, sulfapyridine, sulfadiazine, aminopyrine, thyroid and other antifat preparations, together with any other drugs declared to be dangerous drugs, on a prescription basis.

GOVERNMENT SERVICES

ARMY

SYMPOSIUM ON THE PHYSIOLOGY OF ACETYLCHOLINE

A symposium on the physiology of Acetylcholine is to take place at the Army Chemical Center, Maryland, on April 21. The list of principal speakers and the names of the opening discussants are as follows:

1. The Role of Acetylcholine in Conduction. Dr. David Nachmansohn Columbia University College of Physicians and Surgeons. Opening discussant, Dr. Stephen Krop of the Army Chemical Center.
2. Quaternary Ammonium Ions in Nerve Physiology. Dr. R. Lorente de No, Rockefeller Institute for Medical Research. Opening discussant, Dr. Stephen W. Kuffler, Johns Hopkins University.
3. Acetylcholine as a Pharmacologic agent. Dr. Theodore Koppanyi, Georgetown University School of Medicine. Opening discussant, Dr. Chester Darrow, Institute of Juvenile Research.
4. The Mode of Action of Acetylcholine. Dr. J. H. Welsh, Harvard University. Opening discussant, Dr. Amedeo Marrazzi, Wayne University College of Medicine, Detroit.
5. Action of anticholinesterases on the insect central nervous system. Dr. Kenneth D. Roeder, Tufts College, Boston. Opening discussant, Dr. A. M. Harvey, Johns Hopkins University School of Medicine.

Those expecting to attend should notify Dr. H. E. Himwich, Medical Division, Army Chemical Center, Maryland, prior to April 15. Foreign nationals wishing to attend must obtain prior authority through their Embassy.

"VIRUS X" AND INFLUENZA A

The Army's system of watch posts for influenza was explained by Dr. A. F. Rasmussen Jr., of the University of Wisconsin, during a basic science course being given at the Army Medical Research and Graduate School, Washington, D.C. Watch posts were established over a year ago throughout the United States and at key overseas posts to keep a sharp lookout for influenza. The value of the system was illustrated recently in Los Angeles, when a mysterious epidemic labeded "virus X" spread through the city rapidly. Within a few days Capt. Henry Kempe of the Army had demonstrated that the virus responsible for the respiratory phase of the diseases lumped together as "virus X" was influenza virus A, the same strain responsible for the epidemic of January 1947, but different from the influenza virus of 1943 and 1945.

ARMY BUYS BLIND WORKERS' PRODUCTS

The Army announces that it purchased during 1947 products made by blind workers in the United States worth $1,594,128. Under the act of June 25, 1938 the Quartermaster Corps purchases products from the National Industries for the Blind, a nonprofit agency which facilitates the distribution of such products. Among the products made by the blind and purchased for the Medical Department of the Army last year were 47,232 pairs of sterile gloves; 210,448 sterile wrappers and 15,600 surgical drapes. The products are bought under prices and conditions determined by a Committee on Purchase of Blind-Made Products appointed by the President.

CIVILIAN CONSULTANTS TOUR PACIFIC AND EUROPEAN AREAS

The Surgeon General has announced that a team of civilian medical consultants organized to visit Army hospitals in the Pacific area left March 23 for a five week tour of Japan and Korea. Several similar groups are being established by the Medical Department of the Army to facilitate advanced medical training of army doctors overseas. The visiting physicians will advise hospital staffs and the theater surgeon in the treatment of patients, conduct clinics, make ward rounds and give instruction in their various specialties. The Pacific team is composed of Dr. Milton C. Cobey, associate professor of orthopedics at Georgetown University, Dr. Edmund Horgan, surgeon, Winchester, Va., and Dr. Sam A. Overstreet of the faculty of the University of Louisville, Kentucky. Now in Europe is a team under Dr. Seymour J. Rosenberg, associate professor of psychiatry, Georgetown University School of Medicine; Dr. Alexander Marble, instructor in internal medicine, Harvard Medical School, and Dr. Frederick C. Bost, associate clinical professor of orthopedic surgery, University of California.

The following are scheduled to leave for Europe in March: Dr. Harold Scheie, associate professor of ophthalmology, University of Pennsylvania; Dr. Benjamin Balser, of the neurology and psychiatry department, Columbia University, New York; Dr. Burgess L. Gordon, Jefferson Medical College, Philadelphia, and Col. Frank E. Hamilton, chief, surgical service, Walter Reed General Hospital, Washington, D.C.

NAVY

EXAMINATION FOR APPOINTMENT IN REGULAR CORPS

The Department of the Navy announces that examinations for the selection of candidates for appointment to the grade of lieutenant (junior grade) in the Medical Corps of the Navy will be held at naval hospitals May 3 - 7, 1948. Graduates of approved medical schools in the United States or Canada who have completed intern training in accredited hospitals or who will complete such training within four months of the date of the date of the examination, and who are physically and otherwise qualified, are eligible to take the examination. Candidates, who must be less than 32 years of age at the time of appointment, will be required to appear before boards of medical examiners and supervisory naval examining boards at the Naval Hospital nearest their place of residence to demonstrate their physical and professional qualifications for appointment.

Public law 365 of the Eightieth Congress, approved Aug. 5, 1947, provides additional compensation at the rate of $100 a month for each month of active service performed by officers of the Medical Corps of the Navy. This is in addition to any pay, allowances or emoluments that they are otherwise entitled to receive. Information may be obtained from naval officer procurement offices or from the Bureau of Medicine and Surgery, Navy Department, Washington 25, D.C.

VETERANS ADMINISTRATION

VETERANS ADMINISTRATION NEEDS DOCTORS

The thousands of young resident physicians throughout the country should be interested in a new Veterans Administration program for specialty practice in Veterans Administration hospitals for residents who have finished three years of formal training at an outside institution. Under this program, doctors who have completed approved formal residencies in medicine, surgery and neuropsychiatry may complete the qualifications of their specialty board examinations through supervised practice in their chosen specialty as full time employees of the Veterans Administration. Only in these three specialties have there been thus far assurances of approval by the boards. This arrangement is in operation for residents being trained within the Veterans Administration and is now being extended to offer this opportunity to those residents receiving their formal training at other than Veterans Administration institutions.

In general the specialty boards as a whole require that at least 80 per cent of a candidate's practice be devoted to a specialty for at least two years after completion of his three year formal residency training. In no other place in the country, except Veterans Administration hospitals, can a man practice 80 per cent of the time in a specialty immediately after finishing a three year residency.

For this program, standards are similar to those of the American Medical Association. Candidates are required to be citizens of the United States, graduates of approved medical schools in this country or Canada, to have completed an approved internship and three years of approved formal residency training in a chosen specialty. The successful applicants will have full opportunity to obtain the type and amount of specialty practice required of candidates for certification.

At a recent meeting with board representatives in Chicago, the Veterans Administration agreed that in those hospitals where there is not a board-certified, full time Veterans Administration physician to supervise the residents' activities, the Veterans Administration would arrange for a consultant in the appropriate specialty to check on the residents' work at least once a month and serve in a liaison capacity between the American Boards and the resident. In other words, there will be a thorough and complete supervision and guidance of each man's work.

In general, the hospitals which will participate in this plan are not located in cities where teaching institutions are now connected with the Veterans Administration. This is a program which will take specialty training out into the hospitals where there are not close affiliations with medical schools, although all of the supervising consultants will be connected with medical schools. It will present a definite challenge to these men and will provide an opportunity for them to prove their ability in their chosen field. Although the men need not expect to have separate operating crews as their disposal, or all the assistants a chief has, they will be expected to practice good medicine. In some cases, if a man is good, he might even be made chief of his service in a small hospital. At any rate, they will have from five to ten times as many cases in their respective specialties as they would probably have in a private or university hospital under existing conditions. It should also be pointed out that all veterans' neuropsychiatric hospitals have many general medical and surgical beds, which means a wider opportunity and a greater range of cases than might otherwise be expected.

The Veterans Administration is emphatically not a military institution. A man can come in today and resign tomorrow if he so chooses. The hospital program that the agency is trying to develop can become the greatest medical service organization in the world, and is open to suggestions and constructive criticisms at all times. It is hoped that a fair percentage of these physicians will find the service so satisfying that they will want to stay with the Veterans Administration after they have completed their board requirements, at least until they have earned sufficient reputation to cause some medical school or other institution to want them for what they may consider broader fields. The Veterans Administration can offer these men full time staff appointments in the Department of Medicine and Surgery. They will be taken on in junior, associate, full or intermediate grades, depending on their qualifications. They will receive annual salaries of $4149.60 in junior grade, $4902.00 in associate grade, $5905.20 in full grade and $7102.20 in intermediate grade.

As another decided attraction it may be possible to provide quarters at some of the outlying stations at a modest rate. It must be emphasized, however, that this is completely dependent on each local situation. Rent for housekeeping quarters at these stations generally runs from $40 to $57 per month. Where else can a man get quarters for his family at such low costs these days? Where possible, the agency will try to assign these doctors to hospitals of their choice. In all cases their wishes will be given every possible consideration. In other words, this could be considered an ideal opportunity for the young man with a family who wants to complete his training, give the best type of service and at the same time make a living for his family.

This message is addressed particularly to all residents outside the Veterans Administration, which is going to lose some 1400 or 1500 A.S.T.P. and V-12 trained physicians by July 1. For that reason, it is prepared now to accept applications. Candidates should apply well in advance of the date of availability in order to avoid delay in processing. Their applications must be sent directly to the Branch Medical Director of the Veterans Administration branch areas in which they are interested. The thirteen branch offices are located at Boston, New York, Philadelphia, Richmond, Va., Atlanta, Ga., Columbus, Ohio, Chicago, St. Paul, St. Louis, Dallas, Texas, Seattle, San Francisco and Denver. No street addresses are needed. The Veterans Administration is sending out notices to branch medical directors requesting that they appoint someone in their offices to interview each applicant. If there are no places available in the branch to which application is made, each man will be so notified and his application will be forwarded to Washington, D.C., for possible assignment to another area. It should be emphasized that if any applicant does not receive an acknowledgment within a week or ten days, it does not mean that he is not wanted. These things take a little time, and applicants may be assured that we will process each application just as rapidly as possible. The telephone number of these branch offices will be found in the city telephone directory under U. S. Government, Veterans Administration. Applicants should ask for the branch medical director or his designate.

RESIDENCIES AVAILABLE IN NEUROPSYCHIATRY

A limited number of openings are available at this time for July 1, 1948 appointment to the Veterans Administration residency training program in neuropsychiatry, which is under the jurisdiction of the deans of the Boston medical schools (Harvard, Tufts, Boston University). Training in this program, which may be from one to three years, is given at: Cushing Veterans Administration Hospital, Framingham, Mass.; Bedford Veterans Administration Hospital, Bedford, Mass.; the Mental Hygiene Clinic of Boston, Regional Office of Veterans Administration, Boston, West Roxbury Veterans Administration Hospital, West Roxbury, Mass. and White River Junction Veterans Administration Hospital, White River Junction, Vt.

For information write to Chief Neuropsychiatrist, Veterans Administration Branch Office 1, 55 Tremont Street, Boston 8.

UNSETTLED VETERANS' ACCOUNTS

The deputy veterans administrator for the state of New York and for Puerto Rico announced March 1 that $5,000,000 is being held in reserve by the Veterans Administration to pay doctors and dentists for services to veterans for which no bills have been submitted. The deputy administrator requested that those who had completed treatment of veterans authorized by the Veterans Administration request payment immediately. The huge volume of unsettled accounts is said to be a serious threat to the sound operation of the medical care plan for veterans in the state of New York.

PUBLIC HEALTH SERVICE

EXAMINATION FOR REGULAR CORPS

A competitive examination for appointment in the regular corps of the U. S. Public Health Service in the grade of assistant surgeon and senior assistant surgeon will be held April 5-7 at places convenient to the candidate. Applicants who have passed the National Board Examinations may substitute the results for the written portion of the examination. The oral examination will be held at various points throughout the country. Regular Corps appointments are permanent in nature and provide opportunities to qualified physicians for a life career in one or more of a large number of fields. All applicants must be at least 21 years of age and citizens of the United States, must present a diploma of graduation from a recognized medical school and must satisfactorily pass a physical examination performed by officers of the Public Health Service.

Applicants for the two grades must have had at least seven and eleven years, respectively, of educational and professional training or experience, exclusive of high school.

Entrance pay for an assistant surgeon with dependents is $5,011 a year and for senior assistant surgeon with dependents $5,551 a year. Provisions are made for promotions at regular intervals up to and including the grade of senior surgeon (lieutenant colonel) and for selection for promotion to grade of medical director (colonel) at $9,751 a year. Retirement is authorized at either completion of thirty years' service or age 64.

Application forms may be obtained from Public Health Service Hospitals, District office, or by writing to the Surgeon General, U. S. Public Health Service, Washington 25, D. C.

EXAMINATION FOR NURSES FOR THE REGULAR CORPS

The U. S. Public Health Service announces that examinations for the appointment in grades of junior assistant nurse officer, assistant nurse officer and senior assistant nurse officer in its regular commissioned corps will be conducted throughout the country in some twenty cities. The examination consists of an oral interview, which will be held on various dates from May 4 to June 8; a two day written examination, which will be held June 21, 1948, and a physical examination, which will be at the nearest Public Health Service facility and prior to the oral examination, if possible. The salaries for these officers range from $2955.50 to $3915.50. These figures include allowances for quarters and subsistence.

Appointments to the regular corps are permanent, although officers may resign except during time of war or national emergency. Further information can be obtained from the Surgeon General, U. S. Public Health Service, Washington, D. C. Attention: Division of Commissioned Officers.

RESEARCH WORKERS WANTED

The U. S. Public Health Service's National Institute of Health is seeking scientists for full time clinical and laboratory research on cardiovascular diseases in the National Institute of Health's newly established Experimental Biology and Medicine Institute. Blueprints for a five hundred bed research hospital, to be built on the Bethesda, Md., grounds of the National Institute of Health, call for one hundred and fifty beds for patients with cardiac and metabolic disorders. For the present clinical research is being conducted with twenty-five beds for cardiac patients at the Baltimore City hospitals, in collaboration with the National Institute of Health.

LABORATORY COURSE ON PARASITIC DISEASES

The laboratory division of the Communicable Disease Center, 291 Peachtree Street, Atlanta, Ga., is offering three refresher courses for laboratory personnel in the laboratory diagnosis of parasitic diseases on the following dates: January 12-February 20 (class filled); July 12-August 20; October 11-November 19. While these courses are open to all grades of employed laboratory personnel in hospitals and private laboratories, preference is given to applications from those in laboratories of state and local public health departments. There is no tuition or laboratory fee, but travel and living expenses must be paid by the applicant or his employer. Applications should be made as far in advance as possible. Although laboratory directors and senior staff members may attend these courses, it is proposed to schedule later short courses for persons in these categories.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

ALABAMA

State Medical Meeting at Mobile.—The Medical Association of the State of Alabama will hold its annual session April 15-17 at the Hotel Admiral Semmes, Mobile, under the presidency of Dr. Jesse P. Chapman, Selma. The following will be guest speakers:

Stanley P. Reimann, Philadelphia, Recent Advances in Cancer Research.
Perry P. Volpitto, Augusta, Ga., Use of Sedatives, Hypnotics and Analgesics in General Practice.
Andrew B. Rivers, Rochester, Minn., Perforating Peptic Ulcer.
Robert L. Bennett, Warm Springs, Ga., Adequate Care of Poliomyelitis.
Virgil S. Counseller, Rochester, Minn., Surgical Treatment of Diverticulitis of the Colon.
Henry C. Poncher, Chicago, Pediatric Hematology in Everyday Practice.
Eugene Stead Jr., Durham, N.C., Studies Using the Technic of Venous Catheterization.
Andrew C. Ivy, Chicago, Gallbladder in Health and Disease.
Louis T. Byars, St. Louis, Common Problems in Plastic Surgery.
Edwin C. Ernst, St. Louis, Management of the Treatment of Cancer of the Cervix.
Frank E. Whitacre, Memphis, Tenn., Diagnosis of Ectopic Pregnancy.
Osler A. Abbott, Atlanta, Ga., Modern Methods in Diagnosis and Treatment of Mediastinal Masses.
John S. La Due, New York, Diagnosis and Treatment of Tumors of the Lymphoid System.
Alexander Hollaender, Ph.D., Oak Ridge, Tenn., Atomic Energy in Its Relation to Biologic Problems.
Champ Lyons, New Orleans, Treatment of Peritonitis with Especial Consideration of Chemotherapy.
Mr. Owen Cooper, Jackson, Miss., Functions of a Public Relations Program.

ILLINOIS

Neuropsychiatric Conference.—A postgraduate conference in neuropsychiatry will be presented at Dixon State Hospital, Dixon, March 31 by the Illinois departments of Public Welfare and Public Health and the Illinois State Medical Society. It is part of an educational program for state hospital physicians and physicians in the general practice of medicine. The program, to begin at 1 p.m., is as follows:

Joseph C. Rheingold, Chicago, The Anxiety State.
Heinz Kohut, Chicago, Psychiatric Consultations in a General Hospital.
William H. Haines, Chicago, The Criminal Psychopath.
David B. Rotman, Chicago, Functions of a Court psychiatrist.
Sophia Schroeder Sloman, Chicago, Fundamentals of Child Psychiatry.
Vladimir G. Urse, Chicago, Interpretation of Revised Mental Health Act.
Roland P. Mackay, Chicago, Common Types of Headache and Their Management.
Lewis J. Pollock, Chicago, Peripheral Nerve Injuries.

Dinner will be served at 6 p.m. at the hospital. The evening speaker will be Dr. William W. Bauer, director of health education for the American Medical Association, "The Nation's Health is Good."

LOUISIANA

Doctor's Day.—March 30 has been designated Doctor's Day in New Orleans by the Woman's Auxiliary of the Orleans Parish Medical Society to show appreciation for their services to the community.

State Medical Meeting. — The annual meeting of the Louisiana State Medical Society will be in Monroe April 12-14 under the presidency of Dr. Gilbert C. Anderson, New Orleans: The House of Delegates will meet Monday. At the public meeting Monday night Dr. Morris Fishbein, Chicago, will speak on "A Century of Medical Progress" and Dr. James E. Ayre, Montreal, Canada, will speak. Tuesday's program is made up of two symposiums, one in the morning on cancer and another in the afternoon on medical diseases of the kidney. Guest speakers will be: Dr. Ira T. Nathanson, Boston, "Influence of Sex Hormones and Castration on Advanced Cancer of the Breast and Prostate," and Harry S. N. Greene, New Haven, Conn., 'Clinical Application of in Vivo Tissue Culture." Five sectional meetings have been arranged for Wednesday. Guest speakers will be: John E. Faber, Rochester, Minn., "Experiences with Anticoagulants in Postpartum Patients"; Frank R. Lock, Winston-Salem, N.C., "Maternal Mortality in the South"; William F. Guerriero, Dallas, Texas, "Gyn-Like Complaints"; W. Ambrose McGee, Richmond, Va., "Advantages of Early Recognition and Treatment of Allergic Disorders in Infancy and Childhood"; George B. Eusterman, Rochester, Minn., "Newer Aspects of the management of the Peptic Ulcer Patient" and Herbert L. Mantz, Kansas City, Mo., "Diagnosis of Tuberculosis."

A roundtable discussion, "Vagotomy: Its Surgical and Medical Aspects," will close the program. The President's Reception will be held at 8 p.m. April 13.

MASSACHUSETTS

Tufts Alumni Dinner. — The Tufts Medical Alumni Association will hold its annual dinner meeting on Wednesday evening, April 7, at the Hotel Somerset, Boston. The guest speaker will be Admiral Luis de Florez, Sc.D., New York, who will talk on "New Engineering Developments in the Science of Medicine."

Harvard to Study Family Life. — The Harvard School of Public Health has appointed the first social worker to its faculty, as part of a new program to study the role of family life in the health of children. Miss Elizabeth P. Rice, clinical professor of the social aspects of medicine at the Yale University School of Medicine, will become assistant professor of medical social work in the department of maternal and child health at Harvard. The new program will emphasize the role of the family in preventing the development of undesirable social habits in children and in discovering unfavorable social factors as they relate to the health of the family.

NEW YORK

Graduate Lectures. — The Medical Society of the State of New York with the cooperation of the New York State Department of Health has arranged graduate instruction for the Madison County Medical Society at the Hotel Oneida, on Thursdays at 8:30 p.m. Dr. Raymond J. Pieri, Syracuse, on April 15 will speak on "Operative Deliveries: the Occipitoposterior Position — Illustrated with Moving Pictures." On April 22 Dr. William J. McNerney, Syracuse, will speak on 'Problems in Physical Diagnosis."

The Hudson County Medical Society in cooperation with Rutgers University will bring six weekly lectures to Jersey City Medical center on Friday afternoons at 4 o'clock beginning April 2. The registration fee is $4. The schedule of lectures is as follows:

April 2, Irving S. Wright, New York, *Use of Anti Coagulant Drugs in Diseases of the Heart and Blood Vessels.*

April 9, Edward Weiss, Philadelphia, *Psychotherapy in Medical Practice.*

April 16, George W. Lewis, New York, *What's New in Dermatology?*

April 23, John H. Garlock, New York, *Recent Advances in Gastrointestinal Surgery.*

April 20, Byron P. Stookey, New York, *Indications for Surgery in Diseases of the Nervous System.*

May 7, Leslie O. Ashton, New York, *Etiology and Treatment of Nutritional Anemias in Infancy and Childhood.*

New York City

Measles Epidemic.—The City of New York Department of Health reported March 4 that cases of measles in the city almost doubled in February, when 3,351 cases were reported as against 1,717 in January. By March 1 a total of 5,068 cases had been reported.

United Hospital Fund Exceeds Goal.—Receipts from the 1947 campaign of the United Hospital Fund of New York were reported to be $4,388,672, nearly $5,000 more than its goal. The fund, which aids eighty-nine voluntary nonprofit hospitals, reports that 20,000 new contributors were added to its roll during the campaign.

Course on Rheumatic Fever.—St. Francis Sanatorium for Cardiac Children, Roslyn, Long Island, has announced a postgraduate course in rheumatic fever and rheumatic heart disease at the Sanatorium from June 1 to 15, 1948. Fee for the course is $75. Applications should be submitted before May 1 directly to the sanatorium.

Report of Greater New York Fund.—The annual report of the Greater New York Fund, issued February 23, showed the distribution of $4,136,419 among four hundred and twenty-three local hospital, health and welfare agencies in 1947. When the fund begins its 1948 campaign April 26, it will seek $14,000,000 to maintain the service of the organization's agencies.

Course for Men Student Nurses.—The first class of men student nurses since September 1942 was admitted by the Mills School of Nursing for Men of the Bellevue Hospital School of Nursing, March 31. This first class can accommodate thirty students, but the September class will number forty. The Mills School of Nursing for Men, established in 1888, became part of the Bellevue School in 1929 and was affiliated with the division of nursing of the New York University College of Medicine in 1942.

Spanish-Speaking Physicians Association.—The International Spanish-Speaking Association of Physicians will present at a meeting at the Waldorf Astoria Hotel March 31, a symposium on scientific surgical and medical films in sound and color. Frank Lahey, Boston, will discuss cancer of the rectum; Alton Ochsner, scaleniotomy for the cervical rib, and J. D. Ullery, cesarean delivery of quadruplets. A Spanish film on the blood in pernicious anemia also will be presented. On May 6 a banquet will be held at the Waldorf Astoria in honor of Dr. J. M. Gershberg in recognition of his completion of twenty years as president of the International Spanish-Speaking Association of Physicians and as its founder. Among the speakers at the banquet will be Dr. Ricardo Alfaro, former president of Panama, and Dr. Alton Ochsner, New Orleans. For tickets ($10 per person) write to the treasurer, Dr. Constantine N. Logotheti, 226 West Seventieth Street, New York.

Dr. Houssay Gives Wyckoff Lectures.—The annual John Wyckoff lectures at New York University College of Medicine were delivered February 16 and 17 by Dr. Bernardo A. Houssay, a 1947 Nobel prize winner and director, Institute of Biologic Research, Buenos Aires, Argentina. Dr. Houssay spoke on carbohydrate metabolism and diabetes, devoting the first lecture to "The Role of the Hypophysis in Carbohydrate Metabolism and Diabetes" and the second to "Alloxan Diabetes." This year's lecture series was the tenth to be given under the John Wyckoff Lectureship established by the Phi Delta Epsilon fraternity. A reception and tea in honor of Dr. Houssay was held in the study of Dean Currier McEwen following the first lecture.

PENNSYLVANIA

State Clinical Pathologists. — The Pennsylvania Association of Clinical Pathologists will hold their spring meeting at Pocono Manor, Penn., April 23-25 under the presidency of Dr. Frederick O. Zillessen, Easton. Papers to be presented will include "What the Clinical Pathologist Should Know About Atomic Energy," "Discourse on Thyroid Pathology," "Moulage Preparations of Specimens" and "Work of the State Laboratories."

PHILADELPHIA

Alumni Dinner.—A special Jefferson Medical College alumni dinner will be held June 23 at 6:30 p.m. during the convention of the American Medical Association in Chicago. The dinner will be at the Sheraton Hotel, 505 North Michigan Avenue. Alumni planning to attend are urged to register in advance by sending their checks for $5 to Dr. William W. Bolton, 535 North Dearborn Street, Chicago 10.

Pittsburgh

Stewart Memorial Lecture.—The R. W. Stewart Memorial Lecture will be given at the rooms of the Pittsburgh Academy of Medicine April 13 by Dr. Lester R. Dragstedt, Chicago, who will speak on "Gastric Vagotomy in the Treatment of Peptic Ulcer."

WISCONSIN

Personal.—Dr. Harry M. Guilford, Madison, epidemiologist of the Wisconsin State Board of Health since 1921, retired January 21.

Surgical Society Meeting.—Dr. Nathan A. Womack, St Louis, was the guest speaker before the Wisconsin Surgical Society in Milwaukee February 14. The morning program consisted of operative clinics at the Veterans Administration Hospital, Wood, and the Milwaukee County Hospital, as well as a dry clinic conducted at the Milwaukee Children's Hospital.

Industrial Health Clinics.—Six counties in the industrialized areas of the state are conducting industrial health clinics developed by committees of various county medical societies, the state medical society and state board of health. On March 31 an afternoon visit to the Fairbanks-Morse plant at Beloit will be followed by a dinner meeting for physicians, industrial nurses, insurance carriers, representatives of management and labor. On April 15, Outagamie and Winnebago Counties will carry on a similar program at the Kimberly-Clark mill at Neenah. Racine and Kenosha Counties on April 21 are conducting a clinic in Racine, and on May 6 a clinic is planned for Dane County. Physicians who are not located in any of the counties serving as hosts for the clinics and who wish to attend may communicate with the State Medical Society, 917 Tenney Building, Madison 3, for details.

GENERAL

Public Health Nursing Week.—The fourth National Public Health Nursing Week, sponsored by the National Organization for Public Health Nursing, will be celebrated April 11-17. The campaign this year will center attention on the importance of community cooperation in public health nursing. The two major objectives are (1) to make the work of the public health nurse known to every person in the United States and (2) to recruit to this branch of nursing an increasing number of young women.

Serum Globulin Available for Treatment of Measles.—Dr. Ross T. McIntire, administrator of the American Red Cross National Blood Program, is reported to have said that thousands of vials of immune serum globulin are available for distribution among physicians, hospitals and clinics to combat measles, which is present in epidemic form in some parts of the country. In January and February 85,790 vials were distributed. When the supply of Army-Navy surplus plasma, from which globulin is fractionated, is exhausted, blood which is being donated to the American Red Cross will be used to meet the demand.

Fellowships in Hematology.—The Hematology Research Foundation invites applications for the Ruth Reader Fellowship and the Robert L. Goldblatt Fellowship for research in blood diseases in the academic year 1948-1949. The stipend for each fellowship is $1,500 per year with the option to renew. This offer is made to workers of any race, creed or color in the United States. Applications must be submitted not later than April 15 to Hematology Research Foundation, 72 East Eleventh Street, Chicago 5. Eight copies of the application are requested. Awards will be announced by the Medical Advisory Council in May 1948. The council will choose the institution in Chicago in which the work is to be done.

Gibbs Prize for Research. — The New York Academy of Medicine announces that $2,000 is available under the Edward N. Gibbs Memorial Prize for original research in diseases of the kidney during 1948. Candidates must be physicians who were graduated at least three years ago and are residents of the United States. They must submit evidence of research already performed and of facilities to prosecute research on the causation, pathology and new methods of treatment of diseases of the kidney. Applications should be addressed prior to April 15 to the chairman, Dr. Walter W. Palmer, Gibbs Prize Committee, Public Health Research Institute of the City of New York, William Hallock Park Laboratory, Foot of East Fifteenth Street, New York 9.

Tri-State Medical Meeting.—The Northern Tri-State Medical Association, representing Indiana, Ohio and Michigan, will hold its annual meeting in Findlay, Ohio, April 13 under the presidency of Dr. Oscar P. Klotz, Findlay, Ohio. On the program will be Captain George N. Raines (MC), U.S.N., Bethesda, speaking on the depressive syndrome in general practice: Herbert D. Adams, Boston, general review of thoracic surgery: Plinn F. Morse, Detroit, clinical pathologic conference; Thomas E. Jones, Cleveland, resumé of surgical treatment of peptic ulcer; C. Wesley Eisele, Chicago, diagnosis and treatment of brucellosis, and Dallas B. Phemister, Chicago, treatment of ununited fractures. The luncheon address will be given by Dr. Roscoe L. Sensenich, South Bend, Ind., President-Elect of the American Medical Association.

Grants For Research in Reproduction.—The Committee on Human Reproduction of the National Research Council, acting for the National Committee on Maternal Health, Inc., will entertain application for research in the field of reproduction. Applications to become effective July 1 will be received until May 1; applications to become effective October 1 will be received until August 1. For 1948-1949, the committee will place emphasis on investigations of the factors controlling conception, fertility and sterility, but other fields of endeavor will be supported if projects of special significance are presented. The National Committee on Maternal Health has advised the National Research Council that it proposes to solicit funds to finance the program of research recommended by the Committee on Human Reproduction to an amount of about $200,000 for 1948-1949. Communications regarding grants should be addressed to the Committee on Human Reproduction, National Research Council, 2101 Constitution Avenue N.W., Washington 25, D.C.

Morning lectures will be given on Wednesday and Friday and panel discussions will be held from 12 to 1:15 p.m. beginning Tuesday. The annual convocation will be at the Fairmont Hotel, 8:30 p.m. Wednesday. Dr. Alan Gregg, New York, will speak on "The Golden Gate of Medicine" and Frederick P. Woellner, LL.D., Los Angeles, on "A Philosophy of Trouble" at the banquet at the Fairmont Hotel, 8 p.m. Thursday.

College of Physicians Meeting in San Francisco.—The American College of Physicians will hold its annual session in San Francisco April 19-23, with headquarters at the Civic Auditorium, under the presidency of Dr. Hugh J. Morgan, Nashville, Tenn. The opening scientific address will be the James D. Bruce lecture on preventive medicine, "The Challenge of Preventive Medicine," to be delivered by Dr. James S. Simmons, Boston. Those to address the general sessions by invitation include the following:

Karl A. Menninger, Topeka, Kan., Revisions in in the Concept of Disease.
Hans Selye, Montreal, Canada, The Alarm Reaction and the Diseases of Adaptation.
Stewart G. Wolf Jr., New York, Hypertension as a Reaction to Situational Threats.
John H. Lawrence, Berkeley, Calif., Radioactive Isotopes in Medicine.

Deaths

Clark Moore Johnson San Francisco; born in Normal, Ill.; Nov. 3, 1898; University of California Medical School, San Francisco, 1924; clinical professor of urology at his alma mater; specialist certified by the American Board of Urology, Inc.; member of the American Urological Association; fellow of the American College of Surgeons; an army air cadet during World War I; served in the medical corps of the U. S. Naval Reserve during World War II; affiliated with the Franklin and San Francisco City and County hospitals; chief consultant in urology at the Veterans Administration, 12th District; and of the Bureau of Medicine and Surgery, United States Navy; died January 18, aged 49, of coronary occlusion.

Charles Benjamin Coggin ⊕ Los Angeles; born in Lincoln, Neb., May 12, 1907; College of Medical Evangelists, Loma Linda, 1935; diplomate of the National Board of Medical Examiners; assistant clinical professor of medicine at his alma mater; specialist certified by the American Board of Internal Medicine; an associate of the American College of Physicians; affiliated with the White Memorial and Los Angeles County hospitals; served as an officer in the medical corps, Army of the United States overseas during World War II; died in the University of California Hospital, San Francisco, January 10, aged 40, of glioblastoma.

Pinckney Harral ⊕ San Francisco; born in St Louis, June 22, 1907; Northwestern University Medical School, Chicago, 1933; clinical instructor in orthopedic surgery at the University of California Medical School; affiliated with the University of California and Franklin hospitals; specialist certified by the American Board of Orthopaedic Surgery, Inc.; member of the American Academy of Orthopaedic Surgery; served in the medical corps of the U. S. Naval Reserve during World War II; died January 4, aged 40, of burns received while extinguishing a fire at his home in Mesa, Ariz.

William Murray Ennis, Brooklyn; born in Brooklyn June 19, 1888; University School of Medicine, New York, 1910; member of the American Medical Association; fellow of the American College of Surgeons; served during World War I; formerly assistant clinical professor of surgery at the Long Island College of Medicine; consulting surgeon, Kings County Hospital; on the courtesy staffs of the French Hospital and St. Peter's Hospital, where he died Dec. 26, 1947, aged 59, of fracture of the right femur and bronchopneumonia.

John Henry Graves ⊕ San Francisco; born Oct. 6, 1867; Cooper Medical College, San Francisco, 1896; past president of the California State Medical Association and of the San Francisco County Medical Society; past president of the state board of health; member of the House of Delegates of the American Medical Association in 1921; served as medical director of the state industrial accident commission and state compensation insurance fund; affiliated with St. Francis Hospital; died January 9, aged 80, of carcinoma of the bladder.

Willis Orville Nance ⊕ Chicago; Bellevue Hospital Medical College, New York, 1893; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; at one time alderman and trustee of the sanitary district; a member of the "Fifty Year" Club of the Illinois State Medical Society; formerly a member of the staffs of the Illinois Eye and Ear Infirmary and the Cook County Hospital; died in St. Vincent's Hospital, Los Angeles, January 16, aged 76, of pneumonia.

William J. Adamson, Lincoln, Neb.; Lincoln Medical College of Cotner University, 1903; died January 3, aged 85, of arteriosclerosis and hypostatic pneumonia.

Anson C. Alexander, Penacook, N.H.; Hahnemann Medical College and Hospital of Philadelphia, 1881; member of the American Medical Association; died January 3, aged 92.

J. Lloyd Alexander, Winnett, Mont.; the Hahnemann Medical College and Hospital, Chicago, 1893; member of the American Medical Association; formerly on the faculty of the Southwest School of Medicine and Hospital in Kansas City, Mo.; died January 1, aged 79, of heart disease.

William P. Alexander, Gary, Ind.; Eclectic Medical Institute, Cincinnati, 1891; died in Mercy Hospital Dec. 17, 1947, aged 90.

Warren W. Alger, Algonac, Mich. (licensed in Michigan in 1903); died in November 1947, aged 82.

Oscar Allen, Rosemead, Calif.; College of Physicians and Surgeons, Keokuk, Iowa, 1891; died in January, aged 80.

Charles Grant Augustus, Dayton, Ohio, Ohio State University College of Medicine, Columbus, 1914; affiliated with the Dayton State Hospital, where he died January 4, aged 59, of heart disease.

James Van Horne Ballantyne ⊕ Wilkinsburg, Pa.; University of Pennsylvania School of Medicine, Philadephia, 1909; fellow of the American College of Surgeons; affiliated with the Pittsburgh Hospital and the Columbia Hospital; died January 7, aged 65.

James Glen Beattie, Evansville, Ill.; Barnes Medical College, St. Louis, 1898; died January 14, aged 82.

Albert Francis Bina ⊕ St. Louis; National University of Arts and Sciences Medical Department, St. Louis, 1915; affiliated with Lutheran Hospital, Alexian Brothers Hospital and St. Anthony's Hospital, where he died January 14, aged 63, of hypertensive heart disease.

William Haller Cassell , Wytheville, Va.; Medical College of Virginia, Richmond, 1905; died Nov. 26, 1947, aged 68, of carcinoma.

Charles Joseph Cavanagh , Philadelphia; Jefferson Medical College of Philadelphia, 1899; also a graduate in pharmacy; served during World War I; for many years associated with the city bureau of health and board of education. Died Dec. 15, 1947, aged 73, of cerebral hemorrhage.

William Rufus Chittick, Spring Valley, Calif.; Long Island College Hospital, Brooklyn, 1882; member of the American Medical Association and of the Michigan State Medical Society; at one time practiced in Detroit, where he was president of the Detroit Academy of Medicine, clinical professor of medicine at the Detroit College of Medicine and on the staffs of the Harper and St. Mary's hospitals; died Dec. 25, 1947, aged 89, of heart disease.

Morris Alfred Darbyshire McComb, Ohio; Starling Medical College, Columbus, 1790; for many years a member of the board of education; died Dec. 30, 1947 aged 84, of senility.

Littleton Davis, Roanoke, Va.; University College of Medicine, Richmond, 1909; died January 14, aged 66, of coronary thrombosis.

Maurice F. Doty ⊕ Chicago; College of Physicians and Surgeons of Chiaago, 1895; died in the Cook and Surgeons of Chicago, 1895; died in the Cook County Hospital January 4, aged 82 of injuries received in a fall

Thomas Francis Doyle Chicago; Rush Medical College, Chicago, 1904; member of the staff of the Woodlawn Hospital, of which he had been one of the founders; died January 16, aged 65, of coronary thrombosis.

Roman W. Drostenfels ⊕ Sierra Madre, Calif.; National Medical University, Chicago, 1903; member of the Illinois State Medical Society; died Dec. 30, aged 71.

Orla Andrew Druce, Albany, N.Y.; Albany Medical College, 1909; formerly physician for the New York Central Railroad; died January 15, aged 67, of diabetes mellitus, arteriosclerosis and coronary thrombosis.

Charles Francis Durning, Brooklyn; Columbia University College of Physicians and Surgeons, New York, 1898; member of the American Medical Association; served as medical superintendent of the Coney Island Hospital; died January 14, aged 77.

Henry Edelstein, Cleveland; University of Wooster Medical Department, Cleveland, 1900; also a druggist; died January 1, aged 75, of sarcoma.

Stanley Burt Ellis, Wakefield, Va.; Medical College of Virginia, Richmond, 1903; died in the Petersburg (Va.) Hospital January 2, aged 66, of coronary occlusion.

William Joseph Finnerty, Scranton, Pa.; Jefferson Medical College of Philadelphia, 1925; member of the American Medical Association; served on the staffs of the Mercy, West Side and St. Mary's Hospitals; died Nov. 27, 1947, aged 49, of congestive heart failure.

Virgil Ward French, Riley, Ind.; Indiana University School of Medicine, Indianapolis, 1921; member of the American Medical Association; died in St. Anthony Hospital, Terre Haute, Dec. 9, 1947, aged 56, of paralysis agitans, encephalitis and myocarditis.

Herman C. Frick, Evansville, Ind.; Louisville (Ky.) Medical College, 1900; served as city and county health officer; died Dec. 4, 1947, aged 68, of coronary thrombosis.

Maynard Arthur Froney, Sheboygan, Wisconsin; Milwaukee Medical College, 1904; served overseas during World War I; died Nov. 25, 1947, aged 72.

Walter S. Galloway, Henderson, Ky.; Barnes Medical College, St. Louis, 1897; served on the staff of the Henderson Hospital; died January 1, aged 83, of cerebral hemorrhage.

Cecil Hubert Gibson, South Bend, Ind.; Meharry Medical College, Nashville, Tenn., 1916; died in St. Joseph Hospital, Dec. 22, 1947, aged 59, of cerebral hemorrhage.

Dove Walter Green, Conway, S. C.; Medical College of the state of South Carolina, Charleston, 1912; member of the American Medical Association; served during World Wars I and II; died in the United States Naval Hospital, Charleston, January 16, aged 60, of carcinoma

George A. Green, Nashville, Ill.; St. Louis College of Physicians and Surgeons, 1906; for many years county coroner; member of the American Medical Association; died January 6, aged 70, of cerebral hemorrhage.

Royal Graves Hamilton, Alderwood Manor, Wash.; Rush Medical College, Chicago, 1892; died January 3, aged 88.

Herman P. Harder, Newaygo, Mich.; Northwestern University Medical School, Chicago, 1897; died Nov. 4, 1947, aged 79, of heart disease.

Lexius Henson Harper, Aiken, S. C.; College of Physicians and Surgeons, Boston, 1899; died in Columbia Dec. 9, 1947, aged 71, of lobar pneumonia.

Harold H. Hartley, Terrace, Pa.; University of Maryland School of Medicine, Baltimore, 1903; died January 7, aged 70, of heart disease.

Richard Tullar Henderson, Urbana, Ohio; Starling Medical College, Columbus, 1900, past president of the Champaign County Medical Society; on the staff of the Champaign County Hospital; died January 1, aged 71, of coronary thrombosis.

Caroline Lunetta Hilborn, Robbins, N. C.; Cleveland-Pulte Medical College, 1913; member of the American Medical Association; died recently, aged 81.

Guilford Bert Hoiston, Columbus, Ohio, Ohio State University College of Medicine, Columbus, 1938; mem- of the American Medical Association; served during World War II; affiliated with the University Hospital, White Cross Hospital and the Grant Hospital, where he died January 14, aged 38, of burns received in a gas furnace explosion at his home on Dec. 26, 1947.

Theron Howard Huckins, Tilton, N.H.; Dartmouth Medical School, Hanover, 1902; member of the American Medical Association; affiliated with the Franklin (N.H.) Hospital, where he died January 2, aged 74, of a cerebral accident.

Thomas Willard Kenneth Hume ⊕ Auburn Heights, Mich.; University of Toronto Faculty of Medicine, Toronto, Canada, 1925; served on the staffs of St. Mary's, Herman Kiefer and Henry Ford hospitals in Detroit; died in St. Joseph Mercy Hospital, Pontiac, January 4, aged 46.

Elizabeth Mowat Johnson, Staunton, Va.; Wayne University College of Medicine, Detroit, 1941; served as clinical assistant of psychiatry at the Woman's Medical College of Pennsylvania in Philadelphia; resident physician at the Western State Hospital; died in St. Petersburg, Fla., January 2, aged 39.

Charles P.F. Joyce, Derry Village, N.H.; Dartmouth medical School, Hanover, 1893; died recently, aged 81.

Frank Everts Kellner, Rome, N.Y.; Cornell University Medical College, New York, 1924; diplomate of the National Board of Medical Examiners; served during World War I; died in the Rome Hospital Dec. 25, 1947, aged 51, of cirrhosis of the liver.

Robert Henderson Lewis, Wildie, Ky.; Tennessee Medical College, Knoxville, 1895, member of the American Medical Association; died in the Berea (Ky.) College Hospital Dec. 30, 1947, aged 78.

Jesse Polk Lockhart ⊕ Brady, Texas; Fort Worth School of medicine, Medical Department of Texas Christian University, 1915; served during World War I; died in San Antonio recently, aged 56.

Charles Leverne Macgray Needham, Mass.; Tufts College Medical School, Boston, 1914; member of The New England Pediatric Society; affiliated with the Leonard Morse Hospital, Natick, Newton (Mass.) Hospital and Glover Memorial Hospital; died Dec. 25, 1947, aged 67, of carcinoma of the lungs.

Solomon L. McPherson, Washington, Ind.; Kentucky School of Medicine, Louisville, 1882; member of the American Medical Association; served as state representative and as mayor of Washington; died in Daviess County Hospital Dec. 31, 1947, aged 88.

Arthur Friedrich Marum, New York; Albert-Ludwigs-Universität Medizinische Fakultät, Freiburg, Baden, Germany, 1907; member of the American Medical Association; died recently, aged 64, of coronary thrombosis.

Clarence E. Matlock ⊕ St. Louis; St. Louis University School of Medicine, 1904; served during World War I; affiliated with the Alexian Brothers and St. John's hospitals; died Dec. 30, 1947, aged 64, of aneurysn of the abdominal aorta.

William Jackson Miller ⊕ St. Louis; Marion-Sims college of Medicine, St. Louis, 1892; on the staffs of St. Anthony's, Lutheran and De Paul hospitals; died Dec. 31, 1947, aged 78.

John Wesley Pennington, Pine Bluff, Ark. (licensed in Arkansas in 1904); died Dec. 29, 1947.

Jonathan Bennett Perrine, Grove City, Pa.; past member of the American Medical Association; Medico-Chirurgical College of Philadelphia, 1912; president of the Mercer County Medical Society, of which he had been secretary for many years; served as deputy coroner; died in Akron, Ohio Dec. 24, 1947, aged 58, of coronary thrombosis.

Frederick John Pohle ⊕ Madison, Wis.; University of Michigan Medical School, Ann Arbor, 1934; associate professor of medicine at the University of Wisconsin Medical School; member of the Central Society for Clinical Research; affiliated with the Wisconsin General Hospital; served during World War II; died Nov. 26, 1947 aged 41, of subarachnoid hemorrhage.

John W. Price, Louisville, Ky.; Kentucky School of Medicine, Louisville, 1897; died recently, aged 70, of chronic myocarditis.

Thomas Kevin Reeves ⊕ Pittsburgh; Georgetown University School of Medicine, Washington, D.C., 1925; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; fellow of the American College of Surgeons; served on the staffs of the Pittsburgh and Women's hospitals; died at Dodge City, Kan., Dec. 28, 1947, aged 47.

Lawrence Weldon Rowell, Western Springs, Ill.; Rush Medical College, Chicago, 1900; died January 2, aged 76, of carcinoma of the prostate.

Otto Sasse, Toledo, Ohio; Boston University School of Medicine, 1878; died Nov. 28, 1947, aged 92, of coronary occlusion.

George A. Snyder ⊕ Altoona, Pa.; Jefferson Medical College of Philadelphia, 1928; served during World War II; affiliated with the Mercy Hospital; died Nov. 18, 1947, aged 47, of heart disease.

Jeanne Cady Solis, Ann Arbor, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1892; member of the American Medical Association; died in the Mercywood Neuropsychiatric Hospital Dec. 18, 1947, aged 80, of senility.

William Thompson Stafford, Madison, Wis.; University of Wisconsin Medical School, Madison, 1942; interned at Kansas City General Hospital in Kansas City, Mo., where he served a residency at Kansas City Municipal Tuberculosis Hospital; served on the faculty of the University of Wisconsin; member of the American Medical Association; died Dec. 16, 1947, aged 34.

John Henry Terrell ⊕ Toccoa, Ga.; Atlanta College of Physicians and Surgeons, 1901; formerly mayor of Toccoa and city councilman; affiliated with the county board of health; on the staff of the Stephens County Hospital; died Nov. 19, 1947, aged 69, of heart disease.

William Lincoln Thompson, Bayard, Iowa; Rush Medical College, Chicago, 1894; member of the American Association, died in St. Vincent's Hospital, Los Angeles, Dec. 16, 1947, aged 85, following a prostatectomy.

Adolph Nicholas Thoms ⊕ Cedar Falls, Iowa; John A. Creighton Medical College, Omaha, 1916; served during World War I; died Dec. 15, 1947, aged 55.

George Montgomery Trezevant, Monroe, La.; Louisville (Ky.) Medical College, 1901; died Nov. 13 1947, aged 68, of bronchopneumonia.

Landon Davies Walker, Charlotte, N. C.; Medical College of Virginia, Richmond, 1908; member of the American Medical Association; died Dec. 1, 1947, aged 64, of heart disease.

Lindsay O. Walters ⊕ Muncie, Ind.; St. Louis College of Physicians and Surgeons, 1899; served on the staff of Ball Memorial Hospital; died in Winter Park, Fla., Dec. 27, 1947, aged 74, of coronary thrombosis.

Elizabeth F. Collins Whitehead, Ingleside, Va.; Woman's Medical College of Pennsylvania, Philadelphia, 1899; member of the American Medical Association; died Nov. 27, 1947, aged 73.

Louis Gilbert Wehrle ⊕ Chicago; Bennett Medical College, Chicago, 1913; medical examiner for the Metropolitan Life Insurance Company; died January 13, aged 67, as the result of a fall on the ice.

DIED WHILE IN MILITARY SERVICE

John Dibble ⊕ Lieutenant Colonel, M. C., U. S. Army; born in Camden, N. J., May 24, 1890; University of Pennsylvania School of Medicine, Philadelphia, 1915; fellow of the American College of Physicians; commissioned as a first lieutenant in the medical corps of the regular U. S. Army in January 1917; promoted through the various grades to that of Lieutenant Colonel in January 1937; completed the course at the Army Medical School in Washington, D. C., in 1917, the advanced course at the Medical Field Service School, Carlisle Barracks, Pa., in 1934 and was graduated from the Command General staff School in 1938; later assigned to duty at Fort Slocum, N. Y.; an honor graduate of the School for Flight Surgeons in 1919 and later assigned to the Office of the Chief of Air Service, Washington, D. C.; from September 1920 to May 1922 served with the American forces in Germany; on his return to the United States became chief of the tuberculosis section, first at Walter Reed General Hospital, Washington, and later at Letterman General Hospital in San Francisco; died Feb. 7, 1943, aged 52, as the result of an airplane accident in the Pacific area, where he had been on active duty.

Tom Titian Flaherty ⊕ Lieutenant Commander, M. C., U. S. Navy, Long Beach, Calif.; University of Southern California School of Medicine, Los Angeles, 1939; appointed to the medical corps of the U. S. Navy as a lieutenant (jg) in July 1938; interned at the United States Naval Hospital in San Diego; served as flight surgeon during World War II at the U. S. Naval Air Station, Corpus Christi, Texas, and with the Second Marine Air Wing, Fleet Marine Force; awarded the Silver Star Medal for conspicuous gallantry and intrepidity in action and the Air Medal for meritorious achievement in aerial flight as crew member; died April 11, 1945, aged 36, as a result of an airplane crash at Okinawa Shima, Ryukyu.

Jesse Raymond Battenfeld ⊕ Lieutenant, Medical Corps, U. S. Navy, Kansas City, Mo.; University of Pennsylvania School of Medicine, Philadelphia, 1941; interned at the Hospital of the University of Pennsylvania; diplomate of the National Board of Medical Examiners; appointed a lieutenant (jg) in the medical corps of the U. S. Navy in October 1942; served as a flight surgeon during World War II at the U. S. Naval Air Station, Pensacola, Fla., and in Fighting Squadron 51, U. S. S. San Jacinto; died Feb. 15, 1945, aged 29, in an airplane accident in Kittitas County, Washington.

John Robert Davenport, Holdenville, Okla.; University of Arkansas School of Medicine, Little Rock, 1933; interned at the U. S. Marine Hospital in New Orleans and the Deaconess Hospital in Cincinnati, where he served a residency; entered the medical reserve corps of the U. S. Army in May 1934; promoted to the rank of captain on April 13, 1939, while on inactive status; entered the medical corps, Army of the United States, in August 1940; promoted to major and lieutenant colonel; stationed at the Enemy Alien Internment Camp at Huntsville, Texas, where he died Nov. 21, 1943, aged 39.

John James McNulty, Los Angeles; College of Medical Evangelists, Los Angeles, 1945; interned at the Naval Hospital in Oakland; diplomate of the National Board of Medical Examiners; began active duty as a lieutenant (jg) in the medical corps of the U. S. Naval Reserve in June 1945; died in Hawaii Dec. 2, 1945, aged 26.

THE RESULT OF THE PLEBISCITE

The result of the plebiscite of the whole profession on the National Health Service, taken by the British Medical Association, has been declared. As anticipated, disapproval was registered by an overwhelming majority on a poll of 84 per cent of members. Against the act in its present form 40,814 votes were cast, with 4,084 in favor of it. In every branch of the profession the voting was against the scheme generally by an immense majority. In no single category of fourteen groups was there a majority in favor of the act. The nearest the service came to acceptance was among the group of whole time research workers, where two to one registered disapproval. Even the doctors who have chosen a permanent career in the forces disapproved by sixteen to one. This is noteworthy, for these men have ample experience of control by government, the feature of the act to which the profession most objects. The same is shown by the fact that six of every seven doctors in full time government employ are opposed to the act. Similarly the health officers (who are in full time employment, and who some years ago issued a report in favor of making all physicians salaried officials) having examined the matter further and having studied the implications of the present scheme, voted against it six to one. Of general practitioners, 17,626 disapproved of the act. This makes a majority of 92 per cent in the cases of principals and 88 per cent in the case of assistants.

Commenting on the result, the *British Medical Journal* says that a heavy responsibility now lies with the association not only to the medical profession but to the community generally, which has been given the most exaggerated idea of the medical benefits to be derived from the act.

The *Lancet*, which has always advocated acceptance of the act but with modifications to meet the profession's objections, says that the magnitude of the victory will be a source of strength to the leaders of the British Medical Association and continues:"We do not yet know just what their objective is, or how they intend to use it But if they wish to avoid needless conflict and are prepared to enter into negotiations with the government to that end, the plebiscite gives them a strong position from which to do so. On the other hand, the existence of large belligerent majorities on both sides will not make it easy for negotiators to accept the kind of compromise which the public interest requires." The council of the British Medical Association met to receive the results of the plebiscite and to discuss future action.

ESTABLISHMENT OF A UNIT FOR PREMATURE INFANTS

Prematurity is one of the most important and intractable causes of neonatal mortality. Because specialized methods of treatment have saved many lives, the London County Council decided to establish a unit equipped and staffed for the care of infants born prematurely either in hospital or at home, or in maternity homes not equipped for the care of such delicate patients, or, indeed, not staffed with personnel with the necessary training. The unit has been established at Hammersmity Hospital, which has a large maternity department staffed medically by the Postgraduate Medical School, and where much experience has already been gained in the treatment of premature infants. At a cost of $12,000 the ground floor and first floor of a former staff home have been equipped as accomodation for 20 infants and a certain number of mothers. The accomodation also includes a milk room, a laundry with a bottle sterilizer, an instruction room for mothers, and a dining room for them. The establishment is primarily a research unit, because many of the problems of prematurity are yet unsolved; but it will play a primary part in the arrangements made in the metropolis for premature infants. There is a medical superintendent, and the pediatricians Professors A. Moncrieff, D. de la C. MacCarthy and R.G. Gordon are in charge of the unit.

At the opening ceremony Professor Moncrieff gave as the principal aims in the care of premature infants: (1) prevention of infection; (2) provision of suitable environment, with particular attention to temperature and humidity, and (3) proper feeding. Nursing he regarded as 95 per cent of the battle.

Dr. MacCarthy said that the first aim of the unit was to establish stereotyped conditions in the handling of premature infants. These could then be modified and the effects observed.

NEW QUARTERLY OF NUTRITION SOCIETY

The Cambridge University Press is about to publish for the Nutrition Society the first part of a new quarterly, the *British Journal of Nutrition*, devoted to the publication of reports of original work in all branches of nutrition and incorporating the *Proceedings of the Nutrition Society*, at present published separately. The editorial board will consist of D P. Cuthbertson, J.N. Davidson, R.C. Garry, G. Graham, J. Hammond, E.M.M. Hume, S.K Kon (chairman), I. Leitch, H.S. Platt and J.A.B. Smith. Subscription rates for nonmembers of the Nutrition Society are $12 per volume of four quarterly parts. Separate parts are $4 Papers for publication and letters on editorial matters should be sent to Dr. S.K. Kon, *British Journal of Nutrition*, National Institute for Research in Dairying, Shinfield nr. Reading, Berks, England. Information about the Nutrition Society may be had from the secretary at the same address. Subscriptions to the *British Journal of Nutrition* and inquiries about the quarterly should be addressed to the Cambridge University Press, 200 Euston Road, London, N. W. 1.

COPENHAGEN

(From Our Regular Correspondent)

Feb. 8, 1948.

Movements Among Danish Doctors in 1947

In 1947 one hundred and twenty-five medical students qualified as doctors, and sixty doctors were gathered to their fathers. At the end of the year the membership of the Danish Medical Association was 4,325, nearly every doctor in Denmark being included in this number. There is now one doctor to every 975 inhabitants, but as only 45 per cent of all the doctors are general practitioners, each of them can count on an average clientele of about 2,100 persons. Of these, about 1,600 are over the age of 15 years and are for the most part treated on a sickness insurance basis, so that each doctor has only some 225 prospective patients not so insured.

The tendency for patients to be treated more and more in the hospital and less and less at home or in a doctor's private office is reflected in the growing number of doctors holding hospital appointments and qualifying as specialists in various fields. In 1947 there were twenty-three doctors who took the much-coveted degree of Doctor of Medicine, among them being two women. No fewer than ninety-four qualified for the status of specialist, and among them were six women. For example, in 1947 eleven doctors met the exacting claims for the title of specialist in surgery and seven became entitled to call themselves psychiatrists. Every fourth doctor in Denmark (over 1,100) is now entitled to call himself a specialist in one or more branches of his profession; about four hundred of them hold senior hospital appointments and two hundred, subordinate hospital appointments. Then there are over four hundred specialists holding part time appointments and increasing their income by private practice. Lastly, there are several general practitioners (about eighty) who are also specialists in some field or other. As for the choice between town and country, emigration from the latter to the former is symptomatic of the growing popularity of hospital treatment and of the housing shortage, which is even worse in country than in town.

Awe-Inspiring Examiners and Panicky Examinees

The relation of examiner to examinee has lately been considered once more in the correspondence columns of the journal of the Danish Medical Association (*Ugeskrift for Laeger*). It is a popular subject for discussion, for most of us harbor memories of the wounds inflicted during viva voce examinations. There is a certain type of examiner whose questions have become stereotyped by his having to examine three hundred to five hunderd students every year. There is his examinee counterpart who tries to learn by heart the correct answers to stereotyped questions and who, when the examiner departs from them, becomes hopelessly flustered.

Quite early in the medical curriculum the casualties in Denmark among the students failing to satisfy the examiners are appallingly high, and yet not high enough according to some authorities, who hold that, were the verdict to hinge on the answers given by the examinees, much more than half their number should fail. The problem is to teach the medical student not to cram his brain with minutiae but to grasp his subject intelligently as a whole—In other words, to make him study more and read less. At a recent examination the medical student world was infuriated because one of its members had answered correctly a few standard questions but had been awarded very poor marks on failing to give intelligent answers to questions that required intelligent reasoning. One correspondent suggests that the understaffing of the university is largely to blame for this state of affairs and that in certain subjects four to ten teachers are needed where now there is only one. This reform would enable the teacher to give individual attention to the educational needs of his cramming-addicted class. Another and less expensive suggestion is that examiners should attend the viva voce examinations conducted by their peers in order to get a bird's-eye view of the student's overwhelming problem, which is to satisfy all the examiners, each of whom thinks his own subject is supreme and the subjects of his fellow-examiners of subordinate importance. Doubtless such attendance would be salutary, but who is to enforce it on already overworked examiners?

Tuberculosis Survey in Copenhagen

Data are now available concerning a most instructive tuberculosis survey carried out in 1946 in the population of Copenhagen between the ages of 15 and 34. Invitations were issued to 212,320 persons of this age, and 136,604 responded to undergo mass radiography and tuberculin testing. This tuberculin testing was completed in 112,368 cases, in 22,083 of which the reaction to tuberculin was negative. These negative reactors were advised to have vaccination with BCG, and 15,938, or about 72 per cent of them, consented to this measure.

As with similar surveys elsewhere, several hitherto unknown cases of pulmonary tuberculosis were discovered. In more than half of those with tubercle bacilli in the sputum, there had been no warning symptoms. This survey cost Copenhagen nearly a million kroner (kr. 827,000) or about 1,600 kroner per case of tuberculosis, a sum corresponding to two months' treatment in a hospital. Most of the cases found (85 per cent) belonged to the age group 20 to 34, the population between 15 and 20 years of age being remarkably free from tuberculosis. This is attributed in large part to the systematic vaccination with BCG for some years past of tuberculin-negative youngsters at the school-leaving age.

RIO DE JANEIRO, Jan. 23, 1948.

Rectal Biopsy for Schistosomiasis Mansoni

Progress in the diagnosis of Manson's schistosomiasis was perhaps brought about a few years ago when Ottolino and Atencio of Venezuela suggested the rectal biopsy technic with digestion of the fragment by a 4 per cent solution of potassium hydroxide. Recently, Dr. J. Rodrigues da Silva, assistant professor of clinical medicine, and Dr. Nilton Costa, pathologist, of Rio de Janeiro University, published a report on the examination of 100 consecutive patients subjected to rectal biopsy because of chronic hepatosplenomegaly, chronic constipation, diarrhea, ascitis and the like, with the description and discussion of some improvements which they introduced in the technic. With this technic they found eggs of the parasite in 13 patients; while in only 4 of them were eggs discovered by repeated examination of feces. In 1 case in which the examination of feces was positive, two rectal biopsies and the postmortem examination could not reveal the nature of the disease. In using the rectal biopsy technic to ascertain the viability of the eggs in order to control the treatment, Drs. Silva and Costa found it necessary to diminish the degree of digestion of the fragment and even to discard this stage of the technic, since it greatly modified the structure of the eggs. Examination of the material was performed by crushing the fragment between two microscope slides, as previously suggested by Morales, but they discarded as unnecessary the Morales technic of holding the slides together by means of two Hoffman's clamps. With this modified method Silva and Costa were able to recognize three different types of eggs which may be associated with the effectiveness of the treatment: (1) dead or immature eggs from patients intensively treated; (2) alive, mature eggs which may be full sized, with clear contour of a miracidium, or contracted and poorly developed eggs, in many cases correlated with treatment still under way, and (3) smaller, immature eggs, also frequently found in patients under intensive treatment.

Antibacterial Activity of Aspergillus Niger

The antibiotic activity of fungi is still being studied by many researchers. Several of these studies are connected with the genus Aspergillus, whose species niger has been demonstrated, by Foster and by Pinschmidt, to be active against some strains of Staphylococcus aureus. However, until recently, thirty-two different samples of A. niger of the collection of the Oswaldo Cruz Institute have been found to be inactive against Staph. aureus, not only by A. Rocha Fragoso of the institute but also by W. H. Wilkins and G. C. M. Harris of the mycologic laboratory of the Department of Botany, University of Oxford, England. Recently Wilkins and Harris sent to the Oswaldo Cruz Institute fourteen different samples of A. niger from the National Collection of Type Cultures to be tested by Fragoso, by the same method adopted by him in previous studies. The result of this study was published by Fragoso with the following conclusions: (*a*) in the Raulin-Mosseray medium seven strains of A. niger showed total activity with a maximum of 1:10 against Staph. aureus strain 553, strains 1161 and 2390 remaining active during more than forty days; (*b*) the Czapek-Dox medium with 5 per cent of corn-steep did not improve the results obtained with the Raulin-Mosseray medium, and (*c*) in the yeast-peptone medium all the strains were inactive.

Correspondence

FATAL REACTIONS AFTER AMINOPHYLLINE

To the Editor:—I have just read, with great interest, the courageous article by Drs. Bresnick, Woodard and Sageman in which a frank statement is made of three fatal reactions following the intravenous administration of aminophylline (The Journal, February 7, p. 397). These deaths occurred instantaneously and were compared, correctly, by the authors to similar experiences that had occurred with mercurial diuretics.

Once again, I must call attention to the work done by my associates and me regarding the clinical syndrome of "Speed Shock" (*Arch. Int. Med.* 47:259-287 [Feb.] 1931) which may follow the intravenous introduction of any molecule. Though the present clinical descriptions speak of injection at a "slow but unmeasured rate," the manner of the fatalities strongly suggests that the rate was excessive for the molecule and that death is more likely explicable on the basis of "speed shock" than as the result of the pharmacologic action of a xanthine. My reason for stressing this point is to draw attention to the urgent necessity for an avoidance of intravenous medication when other routes are accessible, particularly in the patient who is in a state of physiologic difficulty.

I am convinced that minor degrees of "speed shock" occur with great frequency. I do not know why the reactions are negligible in some, minor in others and occasionally fatal in still a third group of patients unless it is that the functional state of the liver, as indicated by our experiments, is a determining factor.

I am relatively certain that many more deaths occur from "speed shock" than are reported. I wish to commend the authors for their forthrightness in relating their experiences and urge others who have encountered similar tragedies to make official record of their experiences. Most important of all, of course, is the avoidance of "speed shock" through regard for the following principles:

1. Never give an intravenous injection when a drug can be given effectively by any other route.
2. Never inject any molecule, by the drip method, at a rate in excess of 2 cc. per minute.
3. Never inject a complicated molecule at a rate faster than 0.5 cc. per minute.
4. When injections are made by the syringe method, pierce the vein with a 26 or 28 gage needle so that rapid injection is discouraged.
5. When this small caliber needle has entered the vein, inject no more than 0.1 cc. and then wait at least thirty seconds to observe the response of the patient before proceeding.
6. If there is the slightest doubt concerning the patient's condition or any untoward reaction to the initial small injection, hesitate at least ten seconds between the administrations of each succeeding 0.1 cc.

Undoubtedly these precautions seem excessive, but a single experience with death from "speed shock" is sufficient to emphasize to the unhappy observer that intravenous injection is an irrevocable and implacable hazard, at times, under circumstances difficult to comprehend and impossible to anticipate.

Harold Thomas Hyman, M.D., New York.

DIABETES AND ARTERIOSCLEROSIS IN YOUTH

To the Editor:—A recent editorial entitled "Diabetes and Arteriosclerosis in Youth" (The Journal, Dec. 20, 1947, p. 1074) appears to demand certain qualifications. The assertion that the degree of control of hyperglycemia and glycosuria with insulin is the principal factor determining whether vascular damage will occur in a patient with diabetes is definitely open to question. Henry Dolger concludes in a recent report on 200 cases studied over a period of twenty-five years (Clinical Evaluation of Vascular Damage in Diabetes Mellitus, The Journal, Aug. 16, 1947, p. 1289) that "present day treatment of diabetes has failed to avert the accelerated vascular damage, which is an associated phenomenon of the disease and not a complication." He found that in 50 per cent of his patients vascular damage developed after thirteen years regardless of age of onset, severity of diabetes or type of treatment used. His conclusion was that duration of the disease was the most important factor in the development of degenerative vascular changes. I. M. Rabinowitch (*Ann. Int. Med.* 8:1436, 1935) has presented evidence that the fat content of the diet is another major factor in the causation of vascular damage in diabetes. Neither of these important points was mentioned in the editorial.

It is an accepted fact that coronary artery disease is relatively infrequent in women who have not had diabetes, hypertension or both. Many women with coronary disease have easily controlled diabetes which has never been complicated by acidosis, coma or significant glycosuria. It seems unreasonable to assume that other factors than hyperglycemia and acidosis are not responsible for the vascular damage in such mild cases.

An attempt to minimize vascular damage in patients with diabetes by precise control of the blood sugar to normal levels may lead to the dire consequences of hypoglycemia. Because the evidence that uncontrolled hyperglycemia is the principal factor in the production of vascular disease is open to question, it surely appears rational to allow a mild hyperglycemia and glycosuria in older patients to avoid possible acute coronary insufficiency as the result of hypoglycemia.

In conclusion, the editorial's statement that "deficiency of the hormone insulin is the crucial causative factor" in the production of arteriosclerosis overlooks other factors which may be more crucial. Its therapeutic application may lead to dangerous consequences.

Bernard D. Ross, M.D., Miami, Fla.

ENDOMETRIOSIS

To the Editor: --Endometriosis and adenomyosis are now being reported by careful gynecologic surgeons and pathologists in one of five pelves. Many of those reported are symptomless, but fairly regularly the diagnosis is made and conservative surgery is used as therapeusis. Numbers of these patients then are seen by other medical practitioners who do not understand or fail to take cognizance of the implications of the diagnosis of endometriosis. These patients are subsequently placed on estrogen therapy. This therapy in turn can be in the form of minimal doses, which seem not to stimulate the endometriosis much, but I have seen numerous patients who have had large doses of estrogen and who have had decided reactivation of their endometrial symptoms.

I should suggest that, whenever a diagnosis of endometriosis is proved, either at the operating table or in the pathologic laboratory, the patient be instructed that she is never to have estrogenic therapy for any reason whatsoever, unless full cognizance is taken of the possibility of recurrence of the remaining endometriosis and the possible results of such therapy.

MEDICOLEGAL ABSTRACTS

Malpractice: Needle Left in Patient's Body Following Appendectomy.—*The plaintiff sued for damages resulting from* the alleged negligence of the defendant physician. From a directed verdict in favor of the defendant, the plaintiff appealed to the court of appeals of Tennessee.

The plaintiff consulted the defendant physician in 1941 for a condition which the defendant described as chronic bilateral salpingitis. After being treated for this condition symptoms of appendicitis developed and the defendant removed her appendix in June, 1941. Prior to the appendectomy the plaintiff complained of nausea and cramping pains in the region of the appendix. Following the appendectomy she complained of a "sharp, jabbing pain" in her right side in the region of the incision, which pain continued until January 1946, when a needle was removed from the right lower quadrant of her pelvis within the peritoneal sac enfolded in the fat of the omentum. Immediately on removal of the needle she experienced no further pain.

The first question, said the court, was whether or not the plaintiff offered evidence of circumstances from which the jury might conclude that the needle entered the patient's body during the operation. The proof for the plaintiff, said the court, shows that the pain experienced before the operation was a "cramping" pain, whereas immediately after the operation it was a sharp, jabbing pain which would characterize the pain caused by a sharp metal object like a needle; that the same pain persisted until the removal of the needle and immediately ceased; that the seat of the pain after the operation was in the region from which the appendix was removed and there was no bulging or puffing suggestive of an infection; that she lost weight, became nervous and suffered a general deterioration of health after the operation. We think, said the court, that the plaintiff did offer evidence from which a jury might conclude that the needle entered the patient's body during the operation.

The next question, said the court, was whether or not the circumstances offered by the defendant were sufficient as a matter of law to dissipate the inferences flowing from the plaintiff's evidence. The defendant offered in explanation of these circumstances that the pain was caused by the infection of the fallopian tubes but in this connection, said the court, we note that the defendant himself testified that bilateral salpingitis would cause pain in both sides and, as we understand his testimony, pain in the region of the appendix would be higher in the abdomen than pain incident to salpingitis. The physician who removed the needle testified that salpingitis would not cause a sharp pain such as described by the plaintiff after the appendectomy unless the infection of the tubes was in an acute stage, but the defendant described the condition of the plaintiff's ovaries and tubes as showing "evidence of an old inflammatory process." This is not suggestive of an acute infection, continued the court, but, to the contrary, that the condition was chronic rather than acute. We think the explanation offered, at most, made an issue for the jury and was not conclusive of the question whether the pain described was caused by the needle. The defendant also insisted that the needle is not one he would have used in the operation; that it is not a surgeon's needle. But he admitted the possibility that the needle may have entered through the incision during the operation. If it got into the wound during the operation, said the court, it can make no difference what kind of a needle it was, though, of course, the proof that it was not a surgeon's needle tended to overcome the force of the circumstances relied on by the plaintiff and would be proper for the jury to consider. Other possible explanations of the presence of the needle in the plaintiff's abdomen offered by the defendant were: (*a*) that the needle might have been left in a gauze packing by a hospital seamstress; (*b*) that it may have been introduced into plaintiff's body during a curettement in 1943 and migrated to the place where it was found; (*c*) that it may have been swallowed during infancy; (*d*) that it may have entered the body, without causing pain, through the foot or buttocks. When the plaintiff established by credible proof circumstances from which a reasonable mind might infer that the needle entered during the operation, she was entitled to have her case go to the jury unless the defendant offered some explanation which all reasonable minds might agree destroyed the probative force of the plaintiff's evidence. The defendant could not do this by offering evidence that it might have happened in some other way, any more than a plaintiff can have a verdict on such evidence. Proof that a thing might occur in a certain way is not proof that it did in fact. It was for the jury to weigh the probabilities in the light of all the proof and determine the weight of the inferences to be reasonably drawn from the circumstances relied on by the plaintiff in the light of the possibilities or probabilities appearing from the proof offered by the defendant. Because there were possibilities or even probabilities opposed to the circumstantial evidence in the case did not overcome as a matter of law the force of the circumstantial evidence.

Accordingly, the court found that there was circumstantial evidence that the needle entered through the incision and that the explanations and circumstances offered by the defendant were not sufficient as a matter of law to dissipate the inferences favorable to the plaintiff. For this and other reasons the judgment in favor of the defendant physician was reversed and the cause remanded for a new trial.—*Johnson v. Ely, 205 S. W. (2d) 759 (Tenn., 1947).*

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in The Journal March 20 page 843

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I & II.* Various centers, June 21-23. Final date for filing application is May 22. *Part II.* Various centers, April 26-27. Exec. Sec., Mr. Everett S. Elwood, 225 S 15th St., Philadelphia 2. Part III. Various centers, June. Sec., Dr. J. S. Rodman, 225 S. 15th Street, Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Oral.* New York, April 12-15. Sec., Dr. Paul M Wood, 745 Fifth Ave., New York 22.

American Board of Internal Medicine: *Written.* Oct. 18. Final date for filing application is June 1. Asst. Sec-Treas., Dr. W. A. Werrell. 1 West Main St., Madison 3. Wis.

American Board of Obstetrics and Gynecology: *Oral. All Groups. Part II.* Washington, D C., May 16-22. Final date for assignment is April 1. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh 6.

American Board of Ophthalmology: *Oral.* Baltimore, May 20. Chicago, Oct 6. *Written.* Various centers, Jan. 1949 Final date for filing application is July 1, 1948. Sec., Dr. S. Judd Beach, 56 Ivie Rd. Cape Cottage, Maine.

American Board of Orthopaedic Surgery: *Part II.* Chicago, January 1949. Final date for filing application is August 15. Sec., Dr Francis M. McKeever, 1136 W. 6th St., Los Angeles 14.

American Board of Otolaryngology: *Oral.* Chicago, June 15-19 Sec., D. M. Lierle, University Hospital, Iowa City, Iowa.

American Board of Pediatrics: *Oral.* Cleveland, April 23-25. Chicago, June 25-27. Seattle, Sept. 10-12. Atlantic City, Nov. 17-19. *Written.* July 30. Sec., Miss Lea Leonard, 718 Royal Union Bldg., Des Moines, Ia.

AMERICAN BOARD OF PHYSICAL MEDICINE: Parts I and II. Chicago, June 19-20. Final date for filing application is April 17. Sec., Dr. R. L. Bennett, 30 N. Michigan Ave., Chicago 2, Ill.

American Board of Plastic Surgery: Examinations are given in April and November of each year in the home town of applicants Sec., Dr Robert H Ivy, 1930 Chestnut St., Philadelphia.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: Oral. All Groups. San Francisco, October. Final date for filing application is July 15. Sec., Dr. F. J. Braceland, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Surgery: *Written. Part I.* October. Final date for filing application is July 1. Sec., Dr. J. S. Rodman, 225 S. 15th St., Philadelphia

AMERICAN BOARD OF UROLOGY: Chicago, Feb. 12-16, 1949. Sec., Dr. Harry Culver, Route #13, Sunnyside Rd., Minneapolus 4.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

*Diabetes Mellitus in Infants Under One Year of Age: Report of Case and Review of Literature. J. Schwartzman, Margaret E. Crusius and D. P. Beirne.—p. 587.

*Histoplasmin Sensitivity: Results of Studies of Children in Alabama. S. H. Welch and Ruth Berrey.—p. 607.

Diabetes Mellitus in Infants.—Schwartzman and his co-workers report the case of a child aged 8 months with diabetes mellitus and review from the literature 57 cases of infants less than 1 year of age who had this disease. Heredity, infections and disorders of the central nervous system were the main etiologic factors. Early symptoms may be loss of weight, dry or sensitive skin, irritability and/or crystalline deposits on the diapers. Dermatologic conditions, gangrene, cataract, infections of the respiratory tract, acidosis and coma were common complications. The commonest observations at autopsy were atrophy of the pancreas, with decrease in size and number of the islands of Langerhans, and fatty degeneration of the liver. Treatment is based on a diet approaching the normal one, supplemented with insulin and vitamins as needed. The earlier the onset of diabetes mellitus, especially if the patient is under 3 months of age, the worse the prognosis; and the longer the disease has persisted unrecognized and without proper treatment, the poorer the outlook. In all infants with a familial history of diabetes routine dextrose tolerance tests should be made every two months for the first year and every six months thereafter.

Histoplasmin Sensitivity.—Welch and Berrey describe the reactions in histoplasmin and tuberculin tests in 1,200 Negro children and 923 white children. Fifteen per cent of the Negro and 4.4 per cent of the white children had positive reactions to histoplasmin; 19 per cent of the Negro and 8.34 per cent of the white children had positive reactions to tuberculin. Results of roentgenograms of the chest are also given. No person with clinical histoplasmosis was seen in this area.

Syndrome of Aberrant Right Subclavian Artery.—Brean and Neuhauser report the occurrence of congenital heart disease in 2 boys and 3 girls between the ages of 1 year, 9 months and 4 years, 11 months. Three of the congenitally abnormal hearts were clinically and roentgenologically typical of patent ductus arteriosus, 1 being surgically verified. The fourth was a tetralogy of Fallot, surgically verified. The fifth was a congenital abnormality apparently involving an intracardiac shunt. These 5 cases were part of a series of 15 patients on whom the diagnosis of aberrant right subclavian artery has been made. In 1 of the cases of anomalous subclavian artery with coexistence of a patent ductus arteriosus, German measles in the mother in the second month of pregnancy was the evident cause of the congenital abnormalities. It is suggested that anomalous subclavian artery and patent ductus arteriosus are both manifestations of a basic fetal abnormality, induced in at least some cases by virus disease in the early months of pregnancy. The value of a routine barium swallow during roentgenoscopic examination of the heart and lungs is emphasized.

Pulmonary Manifestations of Fatal Histoplasmosis.—Holt reports roentgenologic pulmonary observations in 5 patients, 4 men between the ages of 41 and 60 and 1 woman aged 30, with fatal generalized histoplasmosis. One of these cases is reported for the first time; the others are included as a roentgenologic supplement to previous publications of the University of Michigan. Analysis of data in these 5 patients indicates that the pulmonary changes in histoplasmosis are as varied as the clinical manifestations of the disease. Histoplasmosis belongs to that relatively large group of pulmonary diseases in which the roentgenologist must be content to identify the presence of abnormality, to determine its extent, to describe certain features regarding its appearance and to offer various suggestions regarding its causation without arriving at a definite diagnosis. The possibility of Histoplasma capsulatum as the etiologic agent of chronic pneumonitis should be particularly mentioned when widespread, coarse, granular, parenchymal lesions are encountered. Final diagnosis of histoplasmosis depends on various laboratory procedures directed toward identification of the yeastlike fungus characteristically found in the cells of the reticuloendothelial system.

Eosinophilic Granuloma of Bones.—Ackerman reports 1 case of multiple osseous lesions associated with involvement of the lungs and diaphragm in a man aged 19 Histopathologic study of an affected rib revealed changes characteristic of eosinophilic granuloma. Histopathologic evidence suggests that there is a close relation between eosinophilic granuloma and Hand-Schüller-Christian's disease. The postulation that only cases with lesions classifiable as lipogranuloma be included in the group of Hand-Schüller-Christian's disease appears too rigid. The author's case demonstrated the association of eosinophilic granuloma with pulmonary and diaphragmatic involvement, whereas the cases reported by Versiani and by Thoma emphasized the coexistence of eosinophilic granuloma and the craniohypophysial manifestations of the disease. The clinical history in Ackerman's case is of long duration and the osseous lesions are of considerable standing and, therefore, they contrast with the opinions expressed by some authors that only early lesions exhibit histopathologic features of eosinophilic granuloma and that the subsequent changes occur fairly rapidly. It is suggested that there are significant variations in the evolution of the basic pathologic process and that the clinical manifestations of the disease in its chronic forms depend largely on the localization of the lesions. The involvement of the diaphragm, not previously recorded in the literature, represents another example of a muscular organ which can be involved in the disease. The method of combined diagnostic pneumothorax and pneumoperitoneum again proved of definite value in establishing the anatomic relations of homogenous densities inseparable from the diaphragm.

Roentgen Therapy in Uterine Fibromyoma.—Pfahler treated 4 women between the ages of 24 and 37 who had uterine fibroids of the interstitial type by roentgen radiation. The ovarian regions were protected by lead, and in none of the four was menstruation interrupted. The first patient had four healthy children after the treatment. One died during childhood from causes not related to irradiation; the three others are alive, have been in military service and have been normal in every respect. The second patient gave birth prematurely to two children after the treatment, but premature birth was due to accidental causes not related to the irradiation. The third patient has not been pregnant during the seven and a half years since roentgen treatment between the ages of 35 and 43. The fourth patient became pregnant after the treatment at the age of 32, and now the child is a healthy girl aged 20 In all these patients the fibroid disappeared completely. Pfahler agrees with Macfarlane that the possibility of carcinoma developing in the uterus after radium or roentgen treatment is extremely remote. This possibility does not contraindicate radium or roentgen treatment of myomatous tumors or of climacteric bleeding.

Peripheral Vascular Disturbances.—According to DeBakey and his associates, more refined technics of plethysmography made it possible to carry out accurate quantitative studies of the fluctuations in volume in such peripheral parts as the pinnae, the fingers and the toes. Evidence indicates that there is a continuous shifting back and forth of blood from one part of the body to another, for this "borrowing-lending" mechanism the term hemometakinesia is proposed. There seems to exist a well regulated mechanism which permits the body to utilize its limited total blood volume in the most efficient manner to meet variations in local requirements The essence of this mechanism seems to lie in the control and regulation of the vascular bed, which permits an increase in the volume of blood of one part of the body with a corresponding simultaneous decrease in the volume of blood in another part without any alteration in the total blood volume. It is suggested that these principles of hemodynamics are applicable to the management of peripheral vascular disease, the effective therapy of which is based on improvement in the circulation or an increase in the blood supply of the part. Measures directed toward the improvement of the local circulation by production of dilatation of the entire vascular bed are of doubtful value, whereas measures directed toward local vasodilatation are in conformity with the natural "borrowing-lending" mechanism hemometakinesia). The most effective method of increasing the local blood supply is sympathetic denervation of the affected part. Two cases, selected from a large experience, are reported to illustrate the concept of hemometakinesia and to demonstrate the value of sympathetic denervation as a therapeutic measure in peripheral vascular disease.

Sympathectomy for Obliterative Arterial Disease.—Freeman and his co-workers say that at the same time when Atlas reported disastrous results from sympathectomy one of them had noted similar phenomena in 4 cases. The first patient had thromboangiitis obliterans and had sustained an occlusion of the left iliac artery Immediately following lumbar ganglionectomy the hypesthesia of the left foot became much more extensive. It was thought that the drop in blood pressure during spinal anesthesia and the use of the head-down position to combat this complication accounted for the increase in vascular insufficiency. Some months later, however, extensive gangrene of the dorsum of the foot developed, and amputation was performed The second patient had severe ischemic neuritis after an acute arteriosclerotic occlusion of the left popliteal artery. When she obtained relief from pain with lumbar block, the sympathetic ganglions were excised. The pain which she had suffered for ten months was relieved. However, oscillations at the ankle, which before sympathectomy were barely perceptible, instead of being improved actually disappeared Necrosis of the tissues on the dorsum of the foot necessitated amputation of the leg three months later. The authors classify these 2 cases as belonging to the low vascular tone group in which sympathectomy is not indicated. They conclude that sympathectomy is useful in the treatment of obliterative arterial disease, especially in patients who show evidence of abnormal vasoconstriction. In advanced obliterative arterial disease, however, especially in patients without evidence of abnormal vasoconstriction, sympathectomy may result in gangrene Although the total circulation may be increased after sympathectomy in these cases, much of the blood is probably shunted directly into the veins through the establishment of numerous arteriovenous anastomoses. The nutrient capillary flow may actually be reduced.

Control of Hemorrhage From Heart by Gelatin Sponge.—Jenkins and his associates investigated the possibility of using the gelatin sponge by the patch technic for wounds of the heart. Fifteen dogs were anesthetized with ether and an intratracheal tube inserted. The chest was entered and the heart exposed. A stay suture was passed through the apex of the heart for traction A wound was then made in the right or left ventricle. A sheet of dry, compressed gelatin sponge was applied over the spurting wound and held in place by the operator's fingers with moderate pressure synchronized with the contractions of the heart while traction was made on the suture passed through the apex. Pressure was maintained over the patch for three to five minutes for wounds of the right ventricle and five to thirteen minutes for wounds of the left ventricle. After twenty to thirty minutes the patch was usually firmly adherent. The pericardium was then sutured and the wound in the chest closed When the dry compressed gelatin sponge is applied over the spurting wound it acts first as a tampon to slow down and stop the flow of blood. As the sponge becomes saturated, clotting occurs in the sponge, thus forming a reinforced clot During the clotting process fibrin is liberated, which permits this reinforced clot, or sponge clot, to adhere to the heart Healing progresses under the protective cover of the sponge, which ultimately undergoes absorption. Gelatin sponge may have a place in the treatment of wounds of the heart to control the immediate hemorrhage, as a supplement to suture or possibly as an alternate to suture under special circumstances such as proximity of the wound to a coronary vessel.

Treatment of Peptic Ulcer.—According to Althausen, medical treatment of uncomplicated peptic ulcer produces prompt relief and early healing of the current ulcer in over 90 per cent of cases. Failure of the physician to insist on a strict and sustained regimen decreases the percentage of successful cases and results in early recurrences. Medical treatment contributes nothing toward prevention of recurrences. With few exceptions, peptic ulcer is an incurable disease which must be kept under control by appropriate measures. Recurrences of peptic ulcer are associated with four main inciting causes: physical and mental fatigue, emotional disturbances, dietary indiscretions and respiratory infections. In addition to prescribing an adequate therapeutic regimen the physician has a threefold duty toward the ulcer patient: to instruct him in the true nature of his disease; to convince him of the necessity of long continued preventive measures, and to assist him in readjusting his life for the purpose of avoiding tension. In the event of recurrence of pain due to ulcer the patient should be prepared to resume at once the strict diet and medical regimen and to report to his physician.

Sodium Restriction in Hypertension.—Perera says that for the past three years patients with uncomplicated hypertensive disease have been studied at the Presbyterian Hospital in New York, primarily because of interest in a possible adrenal cortical relationship. The patients were placed on identical daily diets, which contained from 0.7 to 0.8 Gm. sodium chloride a day. To this could be added fixed amounts of salt in weighed shakers. Throughout the study the patients were on a constant fluid intake. Slight but consistent effects of rigid restriction of sodium chloride were observed in 6 hypertensive subjects. Following the establishment of a base line, sodium chloride was restricted for a period of two weeks and in all instances there was a drop in resting blood pressure. A few patients felt slightly improved subjectively or noted relief of headaches. Following a base line period in which there was a daily ration of 4 Gm. of sodium chloride, in 5 of 6 hypertensive patients who were given 15 Gm. per day there was a slight increase in the resting blood pressure. The effect of rigid restriction of sodium chloride on the pressor action of desoxycorticosterone acetate was then tested in 5 patients. Lastly, the effect of twenty-four hours of rigid restriction of sodium chloride in normotensive and hypertensive subjects was studied. It appears that sodium chloride is related in some way to the mechanism of hypertensive vascular disease. Its restriction as a therapeutic measure is still on trial, the harm of such limitation and dietary invalidism often exceeding the benefit.

Industrial Noise and Hearing.—There has been controversy about the effect of industrial noise on hearing. Machle mentions factors responsible for the lack of clear understanding of this problem. Recently the question has been raised as to the compensability of loss of hearing from industrial exposure to noise. The large number of variables make interpretation of isolated cases difficult. The first step should be the institution of preemployment audiometric examination of all workers who are likely to be exposed to high noise levels. Repeated survey of the most exposed groups is indicated, and study of the magnitude and spectrum of noise at various places in the plant should be carried out. Standardized instruments are available.

Cytochemical Mechanisms of Action of Penicillin.—Pratt and Dufrenoy consider it well established that large differences exist in the sensitivity of gram-positive and gram-negative organisms to penicillin. The differences are so large that most infections due to gram-negative organisms are classed as refractory to penicillin therapy, although it is known that many such organisms are inhibited at sufficiently high concentrations of the antibiotic in vitro. The authors describe physical and chemical changes that occur in different parts of penicillin assay plates seeded with gram-positive and gram-negative test organisms. The evidence indicates that penicillin affects aerobic gram-positive and gram-negative organisms through the same chemical systems. However, the concentration at which its effects become manifest is many times greater on plates seeded with gram-negative organisms than on those seeded with gram-positive organisms. The proper use of trace amounts of cobalt lowers the effective threshold on test plates, a fact which may have practical clinical importance as well as theoretic interest, since the same phenomenon has been demonstrated in vivo.

Prefrontal Lobotomy Under Direct Vision.—Scarff and Kalinowsky say that although the technic which Freeman and Watts developed for prefrontal lobotomy recommends itself for its technical simplicity, it is open to objections. To offset these objections Scarff and Kalinowsky have been performing the section of white matter under direct vision. A coronal incision of the scalp is made which crosses the midline just posterior to the coronal suture and passes laterally and slightly forward toward the lateral rim of the orbit. The anterior flap of scalp is then reflected forward, exposing the central two thirds of the coronal suture and the area of the skull immediately before and behind it. A small osteoplastic flap is then turned up on each side of the midline, hinged on the temporal muscle. These flaps straddle the coronal suture and lie about two thirds in front of the coronal suture and one third behind it. The authors describe how the actual section is made and say that leukotomy under direct vision assures a minimal operative mortality and postoperative morbidity. Little change, if any, occurs to the patient's pulse rate or blood pressure during the operation. Within a few hours after operation the patients are usually responsive and fairly well oriented. Stitches are removed on the third postoperative day, and the patient as a rule is out of bed by the sixth or seventh day.

Chlorine Accident in Brooklyn.—Chasis and his co-workers say that in June 1944 leakage from a tank containing liquid chlorine in a Brooklyn street caused many casualties. Four hundred and eighteen persons were examined in eight hospitals, and 208 were admitted for treatment. The authors review observations on a group of 33 patients who were hospitalized for one or two weeks. The symptoms during the first few hours after exposure consisted of burning of the eyes with lacrimation, burning of the nose and mouth with rhinorrhea and increased salivation, cough, choking sensation and substernal pain. These were frequently accompanied by nausea, vomiting, headache and dizziness. The changes in the respiratory tract consisted of tracheobronchitis, pulmonary edema and pneumonia. Tracheobronchitis was evident in all 33 patients, subsiding in most instances in five to seven days. Pulmonary edema, chiefly basilar in location, was observed in 23 of 30 patients. Twelve of the 14 patients in whom pneumonia developed had pulmonary edema. Except in 3 patients, the clinical course of the pneumonia was benign. Respiratory distress and substernal pain generally subsided within the first seventy-two hours but were frequently followed by substernal soreness. Cough, present in every patient at first, disappeared by the end of fourteen days. The abnormal pulmonary features consisted of mottling, patches of irregular density and differences in the aeration of the two pulmonary fields. Arterial oxygen unsaturation was present within eight hours after exposure in 6 of 8 patients selected for examination because of cyanosis and extensive pulmonary involvement. The incidence of pneumonia was higher in patients who did not receive chemotherapy from the start than in those who received sulfadiazine or penicillin from the first day following exposure. Sulfadiazine appears to be the prophylactic of choice. Bronchodilating drugs such as epinephrine and aminophylline were of benefit in relieving respiratory distress and bronchial obstruction when administered early but were without significant effect when administered late. Eleven of the 33 patients who were observed for sixteen months after discharge from the hospital retained no symptoms attributable to exposure to chlorine. Sixteen patients had anxiety reactions with phobias, hysterical phenomena and psychomotor dysfunction persisting for one to sixteen months.

Alcoholism an Occupational Disease of Seamen.—The executive secretary of the Alcoholics Anonymous Seamen's Club, New York, says that at one of the merchant marine rest centers set up during the war by the United States Public Health Service and the United Seamen's Service some members of the medical staff recognized that alcoholism rather than combat fatigue was responsible for the *hospitalization of many* of the men. A treatment program was inaugurated. The men were told that once a person becomes an abnormal drinker he can never drink safely again. This was a *shock to many of* the seamen. When the physicians told the seamen about Alcoholics Anonymous, they were quick to build up excuses. As an alternative the seamen were encouraged to start their own group. The Alcoholics Anonymous Seamen's Club soon developed an intensive program and expanded its activities by giving talks at marine hospitals, schools, union halls and Seamen's Y. M.

C. A.s. Through the many contacts built up at the Sand's Point Rest Center men were formed into groups and introduced to Alcoholics Anonymous and the facts about alcoholism. The author mentions facilities available for the care of alcoholic seamen in the port of New York.

Medical Staff and Hospital. G. W. Waterman.—p. 878.

Psychoses with Trichinosis.—Campbell states that trichinosis can be divided into three stages, invasion, migration and encystment. It is during the stage of migration that the central nervous system may become involved. According to some observers, involvement of the nervous system may develop in as high as 10 per cent of patients with trichinosis. However, the development of psychosis is comparatively rare, the American and English literature reporting only 19 cases. The prognosis in these cases is not good. In one series 6 of 13 died and 2 had residual neurologic damage. Of the 6 cases reported since 1936, half were fatal. The author reports a new case, that of a man aged 30 who became mentally confused. He would stand in one position staring straight ahead; he chewed paper and sticks and voided on the floor; he was restless, agitated, confused and disoriented; complained of vague pains in his leg and buttocks; he rubbed his nose and mouth continually and answered questions in an irrelevant, facetious manner; he was ataxic and limped on his left leg. He had a positive Romberg sign, falling backward and to the left. Deep reflexes were diminished in the left arm and leg. The left abdominal reflex was absent. His confusion gradually cleared, so that after two weeks he was mentally clear and correctly oriented but had no recollection of his acute illness. He improved further and was discharged but was not well enough to work. In follow-up he complained of being more tense, nervous and restless than he was before his illness. Neurologic examination was negative except for some pain in the lower part of his legs.

Influence of Vitamin E on Vascular Disease.—The fact that animal experiments with diets deficient in vitamin E disclosed vascular abnormalities and that vitamin E in the form of tocopherols exerted favorable effects in lesions involving vascular degeneration induced Shute and his associates to try treatment with tocopherols in patients with vascular disease. They report observations on 22 patients with thrombophlebitis or phlebothrombosis. Fresh thrombi are often associated with a low platelet count. Clinical improvement in these patients was coincident with a rise in platelet count. A decrease of platelets and a persisting high sedimentation rate on tocopherol therapy is an indication either of recurrence or extension and demands an increased dose. Should puerperal women be given tocopherols to avoid thrombosis? Such therapy might also promote lactation. Many herniotomies and pelvic operations might benefit from prophylactic dosage. The authors also observed the effect of tocopherols on 13 patients with indolent ulcers of leg and ankle. The response is ascribed to an improvement in local arteriolar circulation and to better utilization of oxygen by the tissues. Of 3 cases of gangrene of the extremities in which the author employed tocopherol, 1 is described in which amputation of both legs above the knee seemed necessary. After tocopherol treatment amputation was no longer necessary. Tocopherol might be helpful in frostbite and immersion foot. The tocopherols should be helpful wherever improved arteriolar circulation or better oxygen utilization is desired. The need for continued treatment at high dosage levels in so many cardiovascular conditions is analogous to the situation encountered in hormone substitution therapy. About 200 to 300 mg. of alpha tocopherol per day seems to be the average therapeutic level.

Heterologous Growth of Cancer of Prostate.—Hovenanian and Deming point out that human prostatic cancer presents a type of malignant growth which may be investigated from the point of view not only of autonomous growth but also of endocrine factors. Guinea pigs were employed as the alien hosts. Specimens for transplantation were inoculated into the anterior chamber of the eye. The successful transplantation heterologously into guinea pigs demonstrates the autonomous nature of this cancer. It has been shown by serial transplantation that prostatic cancer is under the influence of endocrine factors. When transplanted heterologously in male castrated guinea pigs, human cancer of the prostate did not grow. Similarly in human clinical observation cancer of the prostate has not been found in eunuchs. Stimulation of female guinea pigs with small amounts of androgen did not affect the growth of transplanted prostatic tumor, but stimulation of a female with massive doses aided in establishing a successful take of prostatic cancer. Carcinoma of the human prostate heterologously transplanted in guinea pigs lost a fundamental biologic activity, the production of the enzyme acid phosphatase. This fact was demonstrated by the absence of elevation of blood phosphatase level in tumor-bearing animals and absence of stain for phosphatase in sections of tissue removed from the guinea pig's eye. Heterologous transplantation of human prostatic cancer has indicated that the cellular nucleus holds the key to the biologic activity of malignant cells which have become autonomous, disordered in growth and uncontrollable in cellular metabolism.

Hypertrophic Pyloric Stenosis.—Schaffer and Erbes studied hospital records of 248 patients with pyloric stenosis who were admitted to Milwaukee Children's Hospital between June 1924 and May 1947. The Fredet-Rammstedt pyloromyotomy was done on 232 of these and 15 did not submit to operation. Sixteen deaths have occurred in this series, 9 of which were postoperative deaths. The 7 other fatalities occurred among the 15 patients treated medically. The authors stress the diagnostic importance of roentgenologic examination, since physical examination is not completely reliable. They believe that roentgenologic examination is too little used. Early diagnosis and adequate preoperative care are important and have reduced the mortality rate. There has been no death from pyloromyotomy in the last 172 operations at the Milwaukee Children's Hospital. Routine blood transfusions at the time of operation make for a smoother convalescence and a reduction in postoperative complications.

Sympathetic Interruption in Causalgia.—Shumacker and his associates say that interruption of the sympathetic pathways constitutes the most reliable, conservative and safe treatment of causalgia. This study is based on observations on 90 patients with major causalgia. Sympathetic blocks were performed by the introduction of 0.5 per cent procaine with epinephrine into the paravertebral space between the first and second dorsal ganglions in the case of lesions of the upper extremity, between the first and second lumbar ganglions in lesions of the lower extremity. Sympathetic ganglionectomy for the lower extremities was accomplished through an anterior extraperitoneal approach with the patient under spinal anesthesia. The upper extremities were denervated by the posterior preganglionic operation of Smithwick. There were no deaths and no serious complications. Fifty-seven patients were treated by permanent sympathetic interruption. Twenty-one responded well to single or repeated procaine sympathetic blocks. Two patients noted improvement following neurolysis Two patients obtained relief of pain following excision of a neuroma and neurorrhaphy. Eleven patients who subsequently obtained relief of pain from sympathetic procaine blocks had noted no relief after neurolysis, and 3 had observed no relief after neurolysis and neurorrhaphy. Similarly, 13 patients who were benefited greatly by sympathectomy had observed no change in pain following neurolysis, nor had 4 others following neurolysis and neurorrhaphy. In 3 there was a spontaneous subsidence of symptoms. The outcome in 5 patients is unknown. The authors conclude that sympathectomy is a safe and reliable treatment in causalgia. There is little likelihood that repeated procaine blocks will bring about permanent relief if the first injection causes cessation of pain only for the duration of the anesthesia. One should be encouraged to proceed with a course of procaine blocks, however, if the initial injection gives relief prolonged beyond the period of anesthesia or if successive blocks result in increasing periods of freedom from pain.

Treatment of Infectious Mononucleosis.—Park says that the treatment has been entirely symptomatic until his colleague, Dr. David Greer, recalled that Berkley had obtained favorable effects in 4 patients with infectious mononucleosis by the use of convalescent scarlet fever serum. Greer decided to try pooled human blood plasma in a patient with mononucleosis in whom other measures had proved ineffective. The favorable effects obtained with injections of 250 cc of pooled plasma on several successive days led to the use of this method in 11 children acutely ill with infectious mononucleosis. The treatment has been uniformly gratifying.

Radioactive Iodine in Grave s' Disease.—Radioactive iodine is prepared by the nuclear bombardment of tellurium in the cyclotron, using 14 million electron volts deutrons. The principal isotopes produced are I^{130} (with a half-life of twelve hours) and I^{131} (half- life, eight days). From observations in treating 45 patients with diffuse goiters and hyperthyroidism, Chapman believes that radioactive iodine with a half-life of twelve hours is an effective single therapeutic agent. Like other methods of therapy it has certain limitations. Its possible late toxic effects will have to be observed with the passage of time. Contraindications to its use now seem to be pregnancy beyond the first month and disease of the kidneys.

Serologic Diagnosis in Influenza.—Hoyle and Fairbrother point out that the direct isolation of influenza virus from cases of human influenza by inoculation of the ferret or the fertile hen's egg is not always successful. Serologic methods of diagnosis are therefore of great importance. The virus neutralization test is too laborious and technically difficult for extensive use, but two other methods are available: (1) the complement fixation test of Fairbrother and Hoyle (1937) and (2) the red cell agglutination inhibition test of Hirst (1941, 1942). These two tests differ immunologically and do not always give comparable results. The complement fixation test is more satisfactory than the Hirst test for the diagnosis of epidemic influenza. The authors summarize the results of over ten years' experience of the former. They stress that the complement fixation titers of normal human serums are constant at a low level; while the majority of convalescence serums show titers above the normal range. The complement fixation test is species specific, distinguishing between virus A and virus B, but shows no strain specificity such as is seen in the red cell agglutination inhibition test. The complement fixation test is therefore superior to the red cell agglutination inhibition test for the serologic diagnosis of epidemic influenza. The complement fixation test is not suitable to assess the antibody response to vaccination with influenza virus.

Bilateral Zoster: Report of Case. E. W. Prosser Thomas.—p. 910.

Streptomycin and "Sulphetrone" in Tuberculosis.—Madigan and his associates made two studies: The first aimed to assess the efficacy of streptomycin; the second to evaluate the possible synergic action of streptomycin and sulphetrone, in the light of the significant synergic action between the two agents reported in tuberculous guinea pigs by Brownlee and Kennedy. Sulphetrone is 4,4′-bis (gamma-phenyl-N-propylamino) diphenylsulfone-tetrasodium sulfonate. In 17 cases of tuberculosis affecting different organs parenteral streptomycin was given for periods of from thirteen hours to three months. The intramuscular dose of 0.2 to 0.4 Gm. of streptomycin base at four hour intervals gave blood levels of 6 to 16 micrograms per cubic centimeter. The intrathecal dose of 0.2 to 0.4 Gm. injected once daily gave cerebrospinal fluid levels of 3 to 80 micrograms per cubic centimeter after twenty-four hours. In 6 of the 17 cases sulphetrone was also given orally, leading to a blood sulphetrone level of 7 to 8 milligrams per hundred cubic centimeters in 4 cases. Of 4 cases of uncomplicated meningitis treated with streptomycin alone, 1 showed a temporary modification of the usual course of the disease. Within the same group, 1 adult with proved tuberculous meningitis complicated by extensive fibrocaseous pulmonary tuberculosis recovered from the meningitis. Tuberculosis of the lungs did not improve. In 3 cases of miliary tuberculosis of the lungs complicated by tuberculous lesions elsewhere there was radiologic evidence of temporary progression and apparently total regression of the miliary tubercles. In 2 of these cases, in which necropsies were done, histologic study showed that the original tubercles were healed or healing and that acid-fast bacilli were absent. The third patient, who received sulphetrone, also appeared to do better. All twelve strains of tubercle bacilli isolated before treatment were sensitive to streptomycin; all six strains isolated immediately after treatment were five to a hundred times more resistant. In 2 cases (1 of generalized lymphatic tuberculosis, 1 of chronic pulmonary tuberculosis) clinical resistance developed during adequate therapy. The possibility of producing resistant strains which may be stimulated to rapid reproduction contraindicates the administration of streptomycin in the presence of a chronic lesion of lungs or lymph nodes. The intractable nature of tuberculous meningitis and miliary tuberculosis justifies the use of streptomycin.

*Corpulence in Childhood and Adolescence: Clinical Study. H. B. Graham.—p. 649.
Difficulties and Disappointments in Treatment of Pulmonary Tuberculosis by Artificial Pneumothorax. C. Swaine.—p. 658.

Corpulence in Childhood and Adolescence.—Graham discusses constitutional patterns and etiologic factors and the system of treatment he has developed on the basis of a close study of 52 cases of corpulence in childhood and adolescence. He stresses that the cause is predominantly endogenous rather than exogenous. The treatment included oral thyroid medication in unusually large dosage, supported by psychotherapy, dietetic control, congenial physical activities, accurate measurements and periodic observation and supervision. By means of indexes of weight, height and size the efficacy of treatment has been assessed and demonstrated, and by the graphic plotting of statistical data the significance of the results obtained by thyroid therapy has been proved. It is no longer reasonable to blame the children or their parents for the obesity, nor is it justifiable to underfeed the patients or to deny them the benefits of thyroid medication in adequate dosage.

The Ulcer Problem Considered from Standpoint of the Pathologic Reflex. H. J. Zeigert.—p. 608.
Indications for Surgical Treatment of Gastric and Duodenal Ulcers. J. Kirsch.—p. 611.

Prophylaxis of Embolism at Surgical Clinic.—Rehn shows that in order to prevent embolism, stress must be placed on prophylaxis and on combating the growing and the massive thrombus. The influx of prothrombin into the blood stream plays an important part in the development of thrombosis, and prothrombin is regulated by vegetative impulses. The surgical trauma with the related factors of fear and pain exert a great influence on the vegetative system. Climatic changes also have been shown to be associated with an increase in the prothrombin index. All these factors indicate the vegetative nature of the postoperative complications. The clinical execution of prophylaxis involves chiefly the employment of the anticoagulants, heparin and "dicumarol." However, if these substances are used, there is danger of postoperative hemorrhage; for this reason a strict watch must be kept on the prothrombin index and the coagulation time. Prevention of all thromboses is impossible unless all surgical patients are routinely subjected to prophylaxis with anticoagulants, but this is inadvisable. When the control test indicates danger of thrombosis, then prophylaxis must be instituted. At the author's clinic it became possible to avoid embolism, while other postoperative complications were reduced, which seems to indicate that they may be the result of unrecognized thromboses.

Gastroduodenal Ulcer in the Elderly.—Spang is concerned with the form of peptic ulcer that usually occurs at the onset of the period of involution, that is, after the age of 50. A statistical analysis of 4,500 cases of ulcer convinced him that this type of ulcer is increasing. Ulcer in patients over 50 is usually gastric, not duodenal; the ratio of incidence is practically reversed in comparison with that in the younger age groups.

Whereas the peak of frequency for duodenal ulcer is around the age of 30, for gastric ulcer it is around the age of 50. The predominance of ulcer in men decreases, in that with increasing age ulcers develop in more women. Ulcers are larger in size in the older age group. Extremely large ulcers, 5 cm. in diameter, are not a rarity. Other characteristics are a comparatively short anamnesis, lack of periodicity of the pains and a lesser tendency to heal. It is suggested that arteriosclerotic changes in the stomach play a part in the pathogenesis of ulcer in patients over 50, in that such patients frequently have signs of a generalized arteriosclerosis. The author believes that cerebral apoplexy, cardiac or renal infarct and gastric ulcer in elderly persons are related in that all are of arteriosclerotic origin. Predisposition to ulcer even in the aged seems to be found particularly in those of slender build, but the manifestation seems to depend on the combination of this constitutional type with arteriosclerosis.

*Lymph Node Bronchus Perforation in Primary Tuberculosis in Infants. T. Valledor, J. C. Mérida and A. Guernica.—p. 635.

Lymph Node Bronchus Perforation in Primary Tuberculosis.—The subjects of this report were 7 infants and a child 10 years of age. The patients presented fever and symptoms of tuberculosis. The clinical and roentgenologic diagnosis of perforation was verified in 4 cases at necropsy and in 2 cases by bronchoscopy and roentgen examination of the chest. It was found at necropsy that one or more of the hilar and mediastinal lymph nodes were enlarged and caseous. Lymph node perforation into the right main bronchus took place in 2 cases. In the case of the child of 10 years, three young Ascaris lumbricoides were found in the perforating node. Perforation was bronchial, esophageal and pleuromediastinal in 1 case and tracheal in another. Catheterization of the perforated bronchus during bronchography and aspiration of caseous material was followed by recovery of 1 patient. The roentgenogram taken one year later showed a calcified nodule in the middle lobe of the lung. A patient had an emergency tracheotomy with relief of acute dyspnea from perforation. In 2 cases the symptoms of perforation followed a favorable course.

Clinical Importance of Pantothenic Acid in Diseases of Respiratory Organs. E. Stangl.—p. 1249.

*Pathogenesis and Therapy of Ulcus Disease of Stomach with Special Consideration of Vegetative Constitution. H. Fredenhagen.—p. 1251.

Surgical Treatment of Arteritis Obliterans.—Welti treated by lumbar sympathectomy 20 patients with chronic arteritis of the lower limbs, 18 men and 2 women, 16 of whom were over 50 years of age and 4 between the ages of 28 and 45. The first and second ganglions were removed systematically by the retroperitoneal route and the third and fourth ganglions were likewise removed, provided that conditions were favorable. Considerable and permanent improvement occurred in 6 patients, in whom intermittent claudication disappeared and satisfactory vascularization was reestablished. In 14 patients surgical intervention was followed by either temporary or permanent disappearance of pain from decubitus. In some cases sympathectomy delayed amputation and facilitated a more economic one. Sympathectomy secured improved vitality of the involved extremities as well as of the amputation stumps. Favorable results were obtained particularly in the 4 younger patients and in patients with unilateral lesions. Parathyroidectomy may be considered in cases in which sympathectomy fails, provided that the vascular lesions are not too extensive. This operative intervention gave satisfactory results in 2 patients with localized gangrene of the toes in whom lumbar sympathectomy failed.

Vegetative Constitution in Pathogenesis and Treatment of Ulcers of Stomach.—Fredenhagen studied the significance of constitutional factors in 300 patients, 213 men and 87 women, between the ages of 20 to 80 years, 100 with ulcers of the stomach, 100 with duodenal ulcers and 100 with chronic gastritis which in many instances may be considered as a premonitory stage of ulcer disease. Symptoms of vagotonia were observed much more frequently than symptoms of sympathicotonia. The vagotonia was most pronounced in patients with duodenal ulcers and with recurrences of chronic ulcers; vagotonia did not decrease with higher age. Vegetative dystonia may be ascertained by simple methods; it is definitely and frequently associated with the occurrence of ulcers. Thus the assumption has been confirmed that vegetative dystonia represents a constitutional symptom of a disposition toward ulcus disease. By taking this fact into account the early detection of persons who are predisposed to become chronic carriers of ulcers will be feasible. In many cases the duration of the disease may definitely be shortened by early surgical intervention with reduced risk. The vegetative lability may be diminished by resection of the stomach and proper postoperative treatment with continued ulcer diet, administration of "bellergal" (a proprietary compound containing the alkaloids of belladonna, ergotamine tartrate and phenyl ethyl barbituric acid) and by abstinence from nicotine. The preulcerous character of chronic gastritis may likewise be recognized more easily with the concept of the vegetative constitution and early surgical treatment may be performed under certain circumstances.

*Hematogenous Osteomyelitis and Its Treatment. E. Domanig.—p. 789.

Special Form Taken by Pneumonias During Last Year. W. Gröger and E. Treml.—p. 794.

Treatment with Pervitin (N-Methylamphetamine) in Intrauterine Asphyxia. A. Rockenschaub.—p. 797.

Appendix in Region of Flexura Lienalis. A. Dessewffy.—p. 799.

Hematogenous Osteomyelitis.—The observations reviewed by Domanig were made on 159 children and 145 adults who received treatment at his clinic between 1934 and 1946. The genesis and clinical course of hematogenous osteomyelitis is that of an endogenous sepsis, but the sources of this infection are usually obscure, except in cases of osteomyelitis of the calcaneus. In 7 cases of this type there had always been external injuries in the region of the heel. In no case of multiple osseous foci was the author able to ascertain involvement of the calcaneus, and from this he concludes that osteomyelitis of the calcaneus is not of hematogenous origin. Roentgenologic observations as well as boring into the marrow has convinced the author that the disease process of osteomyelitis is not primary in the medullary cavity. Sometimes only the cortex of the bone is involved and the medullary cavity is free from pathologic changes; at other times only the periosteum is involved. The author believes that the disease is really an osteitis, an embolic infection of the bone, which involves limited or extensive parts of the bone, depending on the position of the involved vascular branch. In some cases it may be a panosteitis. A noteworthy aspect is that the epiphyses remain free from infection in osteomyelitis. The clinical picture of osteomyelitis varies greatly. The author briefly mentions the various methods of treatment that have been in use and shows that the introduction of penicillin has greatly improved the prognosis, provided the diagnosis is made early and treatment is begun promptly. He administers penicillin in doses of from 1,000,000 to 2,000,000 units, but he also resorts to blood transfusion and measures that support the circulation. Immobilization in a fenestrated plaster cast is essential. Early administration of penicillin will prevent the complete destruction of the diseased part of the bone, and if the involved area is small complete restoration is possible. More extensive processes require surgical treatment, which is most advantageously carried out during the eighth or tenth week.

Book Notices

Private Enterprise or Government in Medicine. By Louis Hopewell Bauer, A.B., M.D., F.A.C.P., president, Medical Society of the State of New York, 1917-1918. Fabrikoid. Price, $5. Pp. 201, with 2 illustrations. Charles C Thomas, 301-327, E. Lawrence Ave., Springfield, Ill., 1918

"Private Enterprise or Government in Medicine" is a thoughtful presentation of the strengths and deficiencies of our present system of medical care. The author has carefully analyzed the growth of government in medicine and public health. Sickness insurance programs are briefly traced from their earliest inception in Germany through England, Russia, Sweden and other foreign nations With this background the compulsory sickness insurance movement in the United States is exposed for its true worth

The earliest moves relative to compulsory sickness insurance in the United States date back to 1910 and 1911. Yet "little was heard of the subject until after the report of the Committee on the Costs of Medical Care in 1932." This report together with the National Health Survey (1933) and the National Health Conference (1938) have been the primary sources of data for those interested in promoting a compulsory sickness insurance program. Dr. Bauer concludes that "there are four closely related groups which are back of the movement for compulsory sickness insurance. Two of them are composed of small groups of physicians and two are lay groups, although one of the latter has a physician as chairman."

After tracing the compulsory sickness movement in the United States a chapter is devoted to voluntary insurance. Here is shown the part played by the medical society plans, the industrial plans, commercial insurance and the possibilities of such projects as the Health and Hospital Fund of the United Mine Workers Union.

The author also portrays the role of the American Medical Association in improving the health of the people of the United States. "The American Medical Association has done more to improve the standards of medical care, drugs and other therapeutic agents, to raise the standards of hospitals, to further public health, to fight the inroads of nostrums and quackery than all other organizations put together. The very development of the United States Public Health Service was sponsored by the American Medical Association. The Pure Food and Drug Laws have been furthered by that association." Dr. Bauer briefly develops the other activities of the Association and their influence in improving the standards of health care. "The only thing," he states, "which the American Medical Association has steadily and consistently opposed has been compulsory sickness insurance." Presenting facts clearly and concisely, he shows the Association to be progressive, not accepting change for the sake of change, but changing when change appears justified.

The final chapter summarizes the ideals to be met and the method of meeting them. Here is presented a coherent program for meeting the needs of the country for a better distribution of medical care.

In this period of ultimate conclusion between two technics for answering the problem of more medical care for more people in the United States, this volume offers definitive material such as is not so briefly and succinctly available elsewhere. Here the reader will find the background of the problem, some basic facts about the health of our nation and a consideration of the main solutions that have been offered. Here is a clear distinction between those aspects of the problem that are medical and those that are economic.

Dr. Bauer concludes, as will any logically minded person, that we can proceed step by step toward raising still higher the best quality of medical care now avialable anywhere in the world. He recognizes the need for special attention to problems of the aged, including chronic diseases.

The one lack in what is otherwise an exceedingly fine contribution to a highly debated subject is a comprehensive index.

May's Manual of the Diseases of the Eye for Students and General Practitioners. Edited by Charles A. Perera, M.D., Assistant Clinical Professor, College of Physicians and Surgeons, Columbia University, New York. Nineteenth edition. Cloth. Price, $4. Pp. 521, with 387 illustrations. Williams & Wilkins Co., Mt. Royal and Guilford Aves., Baltimore 2, 1947.

Nineteen editions of this work attest its usefulness. Since the last edition Dr. May died, and the present edition is revised and edited by Dr. Perera, who has worked with Dr. May since the fifteenth edition. The new edition emphasizes penicillin therapy, new theories of color vision, the effects of hormones and the studies that have been made of congenital cataract following maternal rubella. A supplement is devoted to the most recent tests of the eye required for military and other governmental services.

Physical Fitness, Appraisal and Guidance. By Thomas Kirk Cureton, Jr., M.A., M.P.E., Ph.D., Professor of Physical Education and Director of the Physical Fitness Research Laboratory of the University of Illinois, Urbana. Assisted by Frederick W. Kasch, B.S., M.S., Director of Physical Education at the Colleges of Medicine, Dentistry and Pharmacy at the University of Illinois, Chicago, and John Brown, B.S., Assistant Director of Physical Education, Colleges of Medicine, Dentistry and Pharmacy, and W. G. Moss, M.S., Ph.D., Instructor in Physiology, College of Medicine, University of Illinois, Chicago. Cloth. Price, $6. Pp. 566, with 129 illustrations. The C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3, 1917.

The physical fitness committee of the professional schools of the University of Illinois tested all the first year students over a period of three years with a battery of tests. The project was cooperative and utilized many of the different departments in the university. The authors begin by defining physical fitness as distinct from emotional, mental and social fitness. They consider the development of the various tests used, the classification of body types, the relation of weight to physical fitness and the significance of tests of the heart rate, the blood pressure and the basal metabolic rate. They then discuss strength, motor fitness and athletic performance. The book is thus a guide to the appraisal of physical fitness and a record of research such as has not been heretofore available.

The Diagnosis of the Acute Abdomen in Rhyme. By Zeta. Cloth. Price, 5s. 6d. Pp. 88, with drawings by Peter Collingwood. H. K. Lewis & Co., Ltd., 136 Gower St., London, W. C. 1, 1947.

An amazing contribution to medical readers is this collection of poems by an author who chooses to call himself or herself Zeta. The book covers such subjects as appendicitis, perforated ulcer, colics and ectopic gestation with rhymes and fanciful illustrations. The rhymes are bad and the book is boresome. For example:

"Now Strangulation of a coil of gut
Means that the blood-supply is from it cut."

and, in a discussion of biliary colics:

"The women say 'tis much worse than the giving birth
to baby
Though which they'd have if given choice, well, that is
just may be."

and finally, on ectopic gestation:

"In seeking for his mate the eager sperm
Up the Fallopian Tube his way doth worm"

accompanied by a picture of the eager sperm with a checked cap and a striped tie.

Office Manual for the Medical Secretary. By Evangeline Markwick, Ph.D., Instructor in Secretarial and Medical Secretarial Studies, Green Mountain Junior College, Poultney, Vermont, Agnes Erickson, M.A., Instructor in Secretarial and Medical Secretarial Studies, Colby Junior College, New London, New Hampshire, and M. Herbert Freeman, Ph.D., Head of Business Education Department, New Jersey State Teachers College, Paterson, N. J. Cloth. Price, $2.40. Pp. 401, with illustrations. The Gregg Publishing Co., 270 Madison Ave., N. Y. 16; 37 S. Wabash Ave., Chicago 3, 1947.

The authors wrote to 539 doctors, sending them a questionnaire on the duties and training considered desirable for a medical secretary. The authors also secured replies from 124 medical secretaries. This book supplies a careful consideration of the job of the medical secretary from many points of view, with a whole chapter on the telephone. It discusses also the stenographic, mailing and filing work of the secretary. Apparently the first class medical secretary will also have information about editing manuscripts, collecting bills, helping with the banking and finance of the office, giving advice on legal matters and perhaps putting in her spare time in the laboratory. A special section provides shorthand forms for medical words and a good deal of information about punctuation and grammar

Infant Nutrition: A Textbook of Infant Feeding for Students and Practitioners of Medicine. By P. C. Jeans, A.B., M.D., Professor of Pediatrics, College of Medicine, State University of Iowa, Iowa City and Williams McKim Marriott, B.S., M.D. Fourth edition. Cloth. Price, $6.50. Pp. 516, with 36 illustrations. The C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3, 1947.

The fourth edition of this popular textbook contains many revisions, especially in the chapters devoted to growth and development, mineral and water metabolism and vitamins. The entire book is well organized and the subjects are discussed clearly and briefly, yet the essentials of infant nutritionals are set down. The print is clear and easy to read. This volume should find increased popularity among medical students, general practitioners and pediatricians.

Medical Addenda: Related Essays on Medicine and the Changing Order. Studies of the New York Academy of Medicine Committee on Medicine and the Changing Order. Cloth. Price, $1.75. Pp. 156. Commonwealth Fund, 41 E. 57th St., New York 22, N. Y.; Oxford University Press, Amen House, Warwick Sq., London E. C. 4, 1947.

The excellent contributions published by the New York Academy of Medicine Committee on Medicine and the Changing Order are supplemented by a number of essays which are thoughtful and which point definitely to current problems in medical affairs. The essays include:

The Doctor Himself, by James Alexander Miller, M.D.
Psychosomatic Medicine, by Louis Hamman, M.D.
Medical Social Work, by Mary Antoinette Cannon and Harriet M. Bartlett
Psychiatric Social Work, by Winifred W. Arrington
Rehabilitation and Convalescence, by Howard A. Rusk, M.D.
Chronic Diseases, by Ernst P. Boas, M.D.

Some of them have appeared in medical periodical literature and are thus elsewhere available.

Antigonadotrophic Substances: Experimental and Clinical Studies on the Formation of Antigonadotrophic Substances Under Treatment with Gonadotrophic Hormones. By Erling Ostergaard. Translated from Danish by Hans Andersen, M.D. Denne Afhandling er af det laegevidenskabelige Fakultet antaget til offentlig at forsvares for den medicinske Doktorgrad, Kobenhavn. Paper. Pp. 184, with 25 illustrations. Ejnar Munksgaard, Norregade 6, Kobenhavn, K, 1942.

This monograph contains an exhaustive review of the published reports on the existence, production and actions of antigonadotropic substances. The author has also included original data from his own investigations, derived both from laboratory and from clinical studies. Considerable attention is paid to immunologic relationships and the specificity of the various antihormones. The author appears to have demonstrated the production of antigonadotropins to heterologous gonadotropins but does not find evidence of their production following administration of homologous gonadotropins. He advances evidence that the gonadotropins are produced in the reticuloendothelial system and, like ordinary antibodies, are found in the globulin fraction of the serum. He also presents data tending to show that the biologically active part of the gonadotropin is a relatively simple chemical compound in combination with a protein component. The clinical studies are interesting because an explanation is offered for the difference in action of various gonadotropic substances in human beings and for the failure, in many instances, to produce therapeutic responses in hypogonadal patients. The author finds that pregnant mare serum gonadotropin will induce antigonadotropin formation in man after protracted treatment, whereas no antihormone appears to be formed following administration of chorionic gonadotropin. He also finds that chorionic gonadotropin is relatively ineffective in combating ovarian insufficiency, but a combination of chorionic gonadotropin and pregnant mare serum gonadotropin is efficacious. Because of antigonadotropin formation, it is recommended that clinical usage be limited to treatments of three-weeks' duration followed by several weeks' rest before instituting another course of treatment. This book is an excellent summary of the present knowledge of antigonadotropins, but it will be of interest primarily to the laboratory endocrinologist rather than to the clinician.

Adventures of the Mind. By Arturo Castiglioni, M.D. Translated from the Italian by V. Gianturco. Cloth. Price, $4.50. Pp. 433, with illustrations. New York: Alfred A. Knopf, 1946.

In an orderly fashion Professor Castiglioni spins the yarn that makes an intriguing pattern of man's attempt to interpret the ageold problems of life, death, disease, magic and changes in personality. Frequent references to Sir J. G. Frazer's monumental book, "The Golden Bough," demonstrate the primitive influence of magic, rites, amulets and talismans on much of man's thinking. Its influence is still operative in the so-called modern thinking of certain cults.

The second part of the book deals with magic during the middle ages. The Chinese developed an intricate system of numbers and letters, calendars and rites. They were so methodical that they described five hundred different kinds of pulse and one thousand different places for acupuncture. American Indian tribes created a wide variety of drugs among the Aztecs such as coca and other narcotics and a systematic mythology as totem birds. A fantastic magic closely interwoven with mysticism and religion became the basis of Hindu magic. Transmutation of life in polyanimalistic forms is still regarded by many Hindus as the normal migration of the soul. The Egyptian placed more reliance on the priest and the magician. In times this gave rise to a series of amulets, symbols and signs; especially favored were those signs inscribed on scarab. A more speculative metaphysical and monotheistic approach was used by the Hebrews.

The third portion of the book carries the story of magic to modern times. Separation of the favorable events of magic as a part of religion and hostile or destructive forces as evils, witches or devils were a refinement and extension of primitive man's beliefs. Following these ideas early scientific experimenters were considered to be dealers in black magic and evil men. Bubonic plague of the fourteenth century was blamed on demons, the stars, corruption of morals and other aspects of black magic. There spread through Europe mass psychosis that consisted of flagellation, St. Vitus dance and other forms, but, thanks to the stern measures of the church, it was finally eradicated. Later the rise of spiritism and finally the awakening of the scientific method led to decreased emphasis on magic. Psychotherapy through suggestions that heal is given in historical perspective. Mass psychology for the relief of natural pent-up individual hostility with the acceptance of primitive political beliefs is convincingly described, and its adoption in some modern civilizations as in Mussolini's Italy, Hitler's Germany and Hirohito's Japan is a more recent proof of its acceptability. Unfortunately some of these beliefs in modified forms are still offered to unsuspecting youth in many countries throughout the world.

Pharmaceutical Arithmetic: A Complete Course in Everyday Problems in Dispensing, Manufacturing and Hospital Pharmacy. By Ignatius J. Bellafiore, Assistant Professor of Pharmacy, St. John's University College of Pharmacy, Brooklyn, N. Y. Second editon. Loose-leaf. Paper. Price, $3.75. Pp. 396, with illustrations. The C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3, 1947.

This volume is a comprehensive exposition of the arithmetical computations with which the pharmacist may be confronted. Designed primarily as a text for a course given by the author, it may be adaptable to other situations. The author has done a thorough job of presenting the subject and has included numerous examples of practical pharmaceutic arithmetic, problems and review questions. He makes the justifiable assumption that most students have never learned or have forgotten all arithmetic and algebra except, perhaps, that two and two usually equal four. The metric system is introduced first and computations involving weights and measures, specific gravity, percentage preparations, dilution and alligation, and temperature conversion are discussed. The more complex apothecary's system is discussed in the second half of the book. The Appendix contains several useful tables. This book should prove useful as a teaching textbook in pharmacy schools, and parts of it could be used to advantage by medical students during a course in pharmacology.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

BRAIN INJURY FROM HIGH SCHOOL BOXING

To the Editor:—Discuss the hazard of boxing wherein the individual gets repeated blows on the head, especially if continued over long periods of time. May this punishment result in mental impairment? What is the literature covering this subject.

H. F. Schroeder, M.D., Marinette, Wis.

Answer.—A great number of physicians and physical educators have become convinced that boxing cannot be defended as an appropriate sports activity for high school boys.

A. H. Steinhaus (Statement on Boxing in High Schools, *J. Health & Phys. Educ.* **15:**384, 1944) in reviewing the data on this subject asserts that present knowledge appears to warrant acceptance of the following statements:

1. Any serious head injury even without skull fracture or knockout may be accompanied by pinpoint hemorrhage or other brain injury.
2. Such injuries may be suffered equally by experienced or inexperienced boxers in their first encounter or after long experience.
3. There are many portions of the brain in which destruction of a small amount of nerve tissue does not cause paralysis or other noticeable changes in behavior. This is especially true in certain subcortical centers . . . and of the cortex where the highest human faculties such as delicate coordination, memory, speech, self control and the power of reasoning are lodged. Subsequent injuries add to earlier ones, since each is permanent. The exact location and extent of each injury and the total of all injuries will determine the extent of loss of mental powers or bodily control.

A great deal of the strength and endurance which has been attributed to boxing comes about as a result of the training program in which the boxer takes part. These activities can be a part of the preparation for participation in other sports or of a broad program of physical education. In boxing the primary target is the head, and the goal is to injure or physically punish the opponent with the knockout as the eventuality. This is at variance with sports in which injury is incidental, as for example in football where the touchdown is the goal and injury only a possible by-product.

E. J. Carroll (Punch Drunk, *Am. J. M. Sc.* **191:**706, 1936) after two years' study of boxers to develop a medical understanding of the problem concluded: "It is probable that no head blow is taken with impunity and that each knockout causes definite and irreparable damage."

Stating that the incidence of mental injury among those who have stayed in boxing long enough is nearly 50 per cent, H. S. Martland (Punch Drunk, *J. A. M. A.* **91:**1103, 1928) added that "this seems to be good evidence that some special brain injury due to their occupation exists."

Ernst Jokl in his book on "The Medical Aspects of Boxing" (Pretoria, South Africa, J. L. Van Schaik, Ltd., 1941) says that "there is no evidence to support the frequent allegation that boxing is a particularly valuable method of developing character, determination and personality . . . that the refusal to realize the danger of boxing is responsible for many a boxer's life being spoiled; that boxing often exerts a brutalizing influence on spectators and that it appeals to the lowest human instincts."

Kenney, Thacker and Gebhart (The Evaluation of Boxing as a College Activity, *Research Quart.* **11:**80, 1940) polled opinion of health service directors in some sixty colleges and universities. Only 15 per cent considered boxing an appropriate high school activity, and slightly more than 50 per cent did not favor the sport for intercollegiate competition.

Proponents of "controlled" boxing for high school boys argue that with heavy gloves, adequate protection and close supervision the activity differs sharply from prize fighting.

However, Steinhaus in the article previously cited raises the following questions in respect to this reasoning and suggests that a single answer "*no*" invalidates boxing as a high school activity:

1. Can the full advantages distinctively credited to boxing be attained short of genuine "all out" boxing?
2. Can the average high school coach or teacher control a large class of boxers to insure safe boxing?
3. Is there available and on hand a thoroughly safe head gear to protect not against head injury, but brain injury?
4. Is the average boy who becomes good in the sport willing to use his skill only in self defense and unlikely to use the sport as an offense in overcoming opponents both in and out of athletic contests?
5. Can a high school teach boxing without at once giving implied approval to amateur boxing tournaments and to the professional ring?

To protect the welfare of high school boys participating in interscholastic activities the Legislative Council of the American Association for Health, Physical Education and Recreation adopted the following resolution (on file in the office of the executive secretary of the American Association for Health, Physical Education and Recreation, Washington, D. C.) in April 1940:

> Whereas, There seems to be an increasing tendency to promote interscholastic boxing in some communities and on the part of some individuals, and
>
> Whereas, Boxing on a highly competitive basis is known to be potentially dangerous to the safety and welfare of boys participating; be it therefore
>
> *Resolved,* That the American Association for Health, Physical Education and Recreation recommends the discontinuance of interscholastic boxing for boys 18 years of age or younger; and be it further
>
> *Resolved,* That this Association shall encourage all school administrators to immediately take steps to eliminate boxing from their interscholastic athletic programs.

DYSPHONIA

To the Editor:—What is the treatment for a boy aged 19 with a very high pitched voice? This began at the age of 14 when his voice "changed," but it has persisted. His voice is sometimes pitched low for a word or two in a sentence but is predominantly high in pitch. The larynx was well visualized with a mirror and abnormality was not noted, except that the cords appeared very tremulous and vibrated at a rapid rate. Could a spray be used to make the cords less pliable? This condition becomes more embarrassing to the patient each year.

M.D., Alabama.

Answer.—A dysphonia changing from a low pitched to a high pitched voice in a boy 19 years of age without visible abnormality other than a bilateral rapid tremor of the vocal cords is probably of psychoneurogenic origin. However, tremors of the vocal cords have been observed in multiple sclerosis, parkinsonism, paresis, encephalitis, syringomyelia, alcoholism and hyperthyroidism. Bilateral jerking movements of the vocal cords have been seen with tetanus, chorea and hydrophobia. These conditions which may produce tremors or jerking movements of the cords should be eliminated as possible etiologic factors before deciding that the dysphonia in this boy is of psychoneurogenic origin.

Local applications or other treatment to the larynx or vocal cords is not indicated.

VIABILITY OF POLIOMYELITIS VIRUS

To the Editor:—How long will the virus of poliomyelitis live on dead animal tissue and excretions at ordinary temperatures; on other articles, such as clothing? Does freezing the virus prolong its life?

M.D., Ind.

Answer.—The virus of poliomyelitis as naturally present in feces or in central nervous tissues will remain viable almost indefinitely if kept at temperatures between minus 20 and minus 70 C. Information with regard to the viability of the virus in other mediums and at room temperature is incomplete; however, it appears that the virus could remain viable under these conditions for at least one or two days.

BILE SALTS FOR CHOLECYSTECTOMIZED PATIENTS

To the Editor:—A patient, aged 44, weighing 193 pounds (87.5 Kg.), had a cholecystectomy because of mild inflammation four years ago. He now feels best on a low fat, high protein diet and 10 grains (0.65 Gm.) of "desicol" with each meal. Without evidence of liver damage should he continue taking the bile salts indefinitely? What is the optimum dose? Can bile taken with his meals cause gastric or bowel irritation or other untoward effects?

M.D., California.

Answer.—Information is not offered here with regard to preoperative symptoms or the consequences which attend deviations from the patient's low fat routine and therapy with bile salts. Persistent symptoms four years after cholecystectomy are unusual. If they do occur, other possible extrabiliary causes (liver or pancreatic disease and functional digestive disturbances) should be suspected.

If there is actual evidence of spasm of Oddi's sphincter or of intermittent interference with the flow of bile, the use of bile salts is justifiable. Otherwise reason for the continued use of bile salts in this case is not perceptible, since normal production of bile salts by the liver is resumed within two or three weeks, even after obstruction of the common bile duct has been present. In the dose mentioned bile salts would not be harmful, even if latent disease of the liver were present. Gastric or bowel irritation is infrequently produced by the preparation mentioned. Dosage is entirely adequate.

HERPES SIMPLEX

To the Editor:—A patient suffers from recurrent herpes simplex which began with an injection of typhoid antigen three years after having typhoid. She now gets three or four attacks of herpes every summer. I have tried moccasin venom without results. Are there any suggestions?

M.D., Massachusetts.

Answer.—There is no one therapy which can be expected to ield results with certainty. However, there are several methods ich give results in a high percentage of cases.

. Smallpox vaccinations have been used a great deal. The eory is that some sort of cross relation exists between the two viruses. This is doubtful. Nevertheless, on clinical grounds many consider that repeated vaccinations (irrespective of whether there are takes or not), given every two to three weeks up to five or six such treatments, will tend to abort the recurrence of herpes or to ameliorate them when they do happen (Foster, P. D., and Abshier, A. B.: *Arch. Dermat. & Syph.* **36**:294, 1937). Keddie, Rees and Epstein (*J. A. M. A.* **117**:1327, 1941) found that one smallpox vaccination was completely ineffective in preventing herpetic attacks after fever therapy.

2. Injection with the virus of herpes simplex has been used. This has been done in various ways. S. B. Frank (*J. Invest. Dermat.* **1**:267, 1938) used a formaldehyde-treated, herpes-infected brain emulsion and believed that he got good results with this product.

3. Autoserum therapy has been used. Blood is taken just as a new crop of vesicles appear. The serum is separated by centrifugation and stored in sterile conditions. Twice a week 0.2 cc. of the autoserum is injected intradermally, the same site being used for four successive injections. The treatment is carried out for ten weeks with three different batches of serum (Thomas, C. C.: *Arch. Dermat. & Syph.* **43**:817, 1941).

4. Roentgen therapy has been used both to abort attacks and as a prophylactic against subsequent attacks. P. Robert (*Dermatologica* **82**:108, 1940; abstracted, Wise, F., and Sulzberger, M. B.: Yearbook of Dermatology and Syphilology, Chicago, he Year Book Publishers, Inc., 1941, p. 430) used two applitions of 155 r with an interval of two weeks between them. lost American dermatologists believe in smaller dosages than those advocated here. A dose of 75 r can be given prophylactically at such times as the patient is going to do or to encounter the things which usually bring on the attacks of herpes, e. g., basking in the sun or the onset of a cold. Many believe that this will abort or suppress the anticipated attack.

CHANGES IN SEDIMENTATION RATE

To the Editor:—Is sedimentation rate reading on citrated blood that has been left standing for twenty-four hours or longer reliable? How does it compare with the reading of freshly citrated blood?

Jack Heyman, M.D., Newark, N. J.

Answer.—Blood that is allowed to stand in citrate or in oxalate solutions, used as anticoagulants, shows a progressive decrease in the erythrocyte sedimentation rate. Usually no change after two to four hours of standing at room temperature occurs. Thereafter there is a progressive decrease in the sedimentation rate, becoming maximum at about twenty-four hours of standing at room temperature. An otherwise rapid sedimentation rate will decrease to normal in most instances. Blood kept in the ice box will remain the same sedimentation rate longer than that kept in the room. Observations of the erythrocyte sedimentation rate should be made within two to four hours of the time the blood sample is obtained.

FROHLICH'S SYNDROME

To the Editor:—I recently saw a boy 9 years of age in my office with large breasts and retracted nipples but no discharge; a tendency to cryptorchidism; central distribution of adiposity, and undeveloped penis. Please recommend treatment for this type of hormonal disturbance.

William B. Roberts, M.D., Concord, Calif.

Answer.—In the absence of evidence of intracranial lesions it would seem that this boy merely simulates a case of Fröhlich's syndrome. These patients usually develop quite normally with puberty, and with loss of weight all signs of glandular dysfunction disappear. However, some physicians prefer to give glandular therapy in order to eliminate any possible psychologic trauma which may develop due to the superficial abnormalities in body appearance. Administration of chorionic gonadotropin, 400 international units twice weekly, for several weeks usually produces a noticeable maturation of the genitals and a descent of the testes, if there are no anatomic barriers. This is usually sufficient to reassure the patient and his parents that there are no sexual abnormalities. It is also advisable to restrict the patient's diet in order to reduce the adipose condition.

BLOOD PRESSURE AND ALTITUDE

To the Editor:—What effect has a change of altitude from sea level to 5,000 feet, or vice versa, on blood pressure?

M.D., Colorado.

Answer.—Such change in altitude should have little if any effect on arterial tension, assuming that the change is not an abrupt ascent and is not associated with anxiety. If the question applies to land altitude, changes in blood pressure can be ignored; if it involves aviation, the element of anxiety must be considered. This latter factor may cause considerable change in arterial tension with great individual variation.

BLACK TONGUE

To the Editor:—A white woman, aged 35, has been suffering severe, knife-like pains in the chest for over one month. Attacks occur one to two times daily; pain is usually in the right side, over the fifth or sixth rib anteriorly. Occasionally pain radiates to the precordial region, to the right shoulder, or to both shoulders. Emesis and nausea are absent. Dyspnea and hoarseness and sometimes complete aphonia accompany the attacks, which last six or seven hours, despite glyceryl trinitrate, atropine, meperidine hydrochloride ("demerol hydrochloride" N. N. R.) in 100 mg. doses repeated after two hours and methadon (6-dimethylamino-4,4 diphenyl-3-heptanone) in one or two doses of 10 mg. After the patient falls asleep the respirations are still labored and often irregular. During attacks swallowing is often difficult, and even water, when sipped, causes coughing and choking. The picture is frightening. I have spent hours with the patient during attacks, and it has required great will power not to give narcotics more frequently than at two hour intervals.

Moderate edema of both ankles occurs. Temperature is usually normal, but often ranges from 100 to 101 F. The tongue has a thick black coating. Eyes show no changes due to vitamin deficiency. There is a moderate cracking or fissuring at each corner of mouth.

On account of hoarseness, a laryngologist examined the patient and found "moderate edema and redness of vocal cords." Inhalations were taken regularly without effect. Antispasmodic drugs in large doses have been taken daily for three weeks, and phenobarbital, 3 to 4 grains (0.19 to 0.26 Gm.) daily, with no effect.

Two internists who examined the patient diagnosed the condition as "functional" (despite the following paragraph) and prescribed sedatives and antispasmodic drugs.

I prescribed daily doses of 300 mg. thiamine chloride and 300 mg. of nicotinamide orally plus daily injections of vitamin B complex (100 mg. thiamine and 100 mg. nicotinamide plus 100 mg. ascorbic acid), and 15 units of refined liver extract. After the injections were given for one week, the patient's tongue was normal. I then stopped all vitamins: one week later the tongue was again covered with a thick grayish black coating. I renewed administration of the preceding medicaments and the tongue is again normal, but there was no effect on the attacks of pain.

What is the suggested diagnosis?

M.D., New York.

Answer.—The black tongue is suggestive of an entity called "hairy black tongue." This is characterized by decided hypertrophy of the filiform papillae and pigmentation believed to be due to a superficial infection with any of a number of pigment-forming fungi or bacteria (Kennedy, C. B., and Howles, J. K.: *Arch. Dermat. & Syph.* **42**:566, 1940). This condition is considered to be of no importance aside from its psychologic effect. It has nothing to do with "black tongue" in dogs, a condition which has, as its human counterpart, atrophy of tongue papillae without pigmentation. The lingual symptoms probably can be dismissed as not being connected with the rest of the picture. Note that the thoracic symptoms did not improve when the tongue did.

It would seem that the patient is not suffering from vitamin deficiency. There are nonvitamin causes for cheilosis. No importance is attached to the slight pigmentation of the hands. Although the pain in the right side of the chest is not characteristic of liver or gallbladder disease, the radiation of pain to both shoulders brings up that possibility.

Considered but deemed unlikely are the following: an intermittent right diaphragmatic herniation, pleurodynia and angina pectoris.

Hysteria could explain the chief clinical features, namely, the aphonia, the difficulty in swallowing, the dyspnea on the basis of a hyperventilation tetany and, possibly, the pain. The presence of a slight temperature weakens this diagnosis. Further study should include the following: serum protein and albumin-globulin ratio (cf. edema), fluoroscopy of the chest during an attack, Graham-Cole test, barium swallow during an attack and rectal temperatures.

"TAMPAX"

To the Editor:—Can "tampax" be inserted in the vagina of virgins for menstrual protection without danger of injuring the hymen to the extent of destroying this evidence of virginity?

John H. Murphy, M.D., Geneseo, Ill.

Answer.—Yes, if the smallest size "tampax" is used.

DRUG THERAPY IN DEGENERATIVE DISEASE

ANDREW C. IVY, M.D.

Vice President of The University of Illinois and Head
of the Department of Clinical Science
Chicago

The term degeneration is used physiologically to refer to a process characterized by an impairment or perversion of the function of a tissue. It should be noted that with this definition cancer would be classified as a degeneration, and the expression "carcinomatous degeneration" of a tissue is not infrequently used.

Morphologically the degenerations form a heterogeneous group of changes in which abnormal materials collect in or between cells, with nonfatal or fatal consequences. The degenerations are believed to be due either to the metabolic disorder of cells, which arise from latent weaknesses in the constitution, or from external causative factors or a combination of both. The morphologic changes consist of "cloudy swelling," or albuminous degeneration, fatty degeneration, glycogen infiltration, amyloid degeneration, hyaline degeneration which involves collagenous connective tissue in arteriosclerosis, mucoid degeneration and the excessive deposit of urates, pigments, calcium and other substances and of the necrosis of cells.

The expression "degenerative diseases," however, refers particularly to the slowly progressive circulatory and metabolic disorders usually associated with aging. In contrast to the infectious diseases of youth, the causation of degenerative diseases appears to be chiefly endogenous, cumulative and multiple, the onset insidious and asymptomatic and the course chronic, progressive and nonimmunizing.[1]

It is rational to distinguish between the "degenerative diseases" and the processes, retrogressive or degenerative, which occur as a natural concomitant of life. Or, in other words, it is rational to distinguish between pathologic aging and physiologic aging.[2] In pathologic aging the degenerations are accelerated by some external or internal environmental factor or factors which, if known, would be subject to control. On the other hand, in physiologic aging, or senescence, the degenerations are viewed as an involution or as a retrogressive process which is as natural as growth. This view would teach that, in the process of living, injurious chemical and physical conditions accumulate because of the imperfect adaptation of the body to its environment, and, as a result, the usual degenerative changes associated with aging occur, including the cancerous processes.

The degenerative diseases, then, are the noninfectious and nonparasitic diseases which kill and maim aging persons prematurely and for which it is biologically rational to hope that the causes, the prevention and better management may be found.

SOME OF THE DEGENERATIVE DISEASES

Some of the more important or better known degenerative diseases will be listed, for purposes of orientation, relative to treatment with drugs. Arteriosclerosis, chronic myocarditis, chronic nephritis, atrophic gastroenteritis, pernicious anemia, diabetes mellitus, cirrhosis of the liver and the pancreas, diverticulosis of the colon, hemorrhoids, senile paralysis agitans, senile psychosis, multiple sclerosis and combined degeneration of the spinal cord, hypertrophy of the prostate gland, dental caries (perhaps), hypertrophic osteoarthritis, postmenopausal or senile osteoporosis, gout, otosclerosis and senile deafness and blindness constitute some of the degenerative diseases. Some would classify cancer and goiter as degenerative diseases. The decline of function of the ovaries and the testes with age represents involution rather than degenerative disease.

DRUGS USED IN THE MANAGEMENT OF DEGENERATIVE DISEASE

The drugs which are used to substitute for specific deficiencies created by the degeneration of organs are relatively few in number and involve, with two exceptions, endocrine products. The specific drugs used to substitute for functions lost as a result of degenerative disease or the natural involution of an organ are: insulin for diabetes mellitus, extract of adrenal cortex for adrenal cortical insufficiency or Addison's disease, thyroid for myxedema and diseases fostered by hypometabolism, extract of liver for pernicious anemia which results from a type of atrophic gastroenteritis, pancreatin for the deficiency of pancreatic juice due to pancreatic fibrosis, estrogens for menopausal symptoms and associated disturbances and cancer of the prostate gland and testosterone to improve the retention of protein and for the treatment of cancer of the breast. All the other drugs used in the management of degenerative diseases act primarily by ameliorat-

[2] Rolleston, H.: Medical Aspects of Old Age; New York, The Macmillan Company, 1932.

ing the symptoms of disease rather than by substituting for a deficiency.

Vasodilators, such as theobromine, theophylline ethylenediamine, the nitrites, erythrityl tetranitrate, bismuth subnitrate, nicotinic acid, papaverine hydrochloride and alcohol, are used to counteract vasospasm or dilate relatively inelastic arterioles.

Sedatives, such as the barbiturates, chloral hy-ate and the bromides, are used in hypertension d coronary disease to promote relaxation and decrease the load on the heart. Drugs which support the heart, such as digitalis, strophanthin and quinidine sulfate, are frequently required. Expectorants, such as potassium iodide and ammonium chloride, are useful in cardiac asthma and emphysema. Diuretics, the purine derivatives, the organic mercurials and ammonium chloride are of value in cardiac edema and some cases of cirrhosis of the liver.

Analgesics, such as morphine for the pain of coronary occlusion and the salicylates for rheumatic pains, prevent much suffering.

Antispasmodics, such as belladonna and stramonium, find a place in the management of paralysis agitans. Colchicine promotes the excretion of uric acid in gout and probably acts on the cause as well as the symptoms.

Antibiotics and sulfonamide drugs will probably retard the development of certain degenerative diseases by shortening the duration and decreasing the severity of infectious diseases.

Though there have been *striking achievements in* the treatment of degenerative disease, the outstanding achievement of medical science has been the control of infectious diseases. This achievement is dramatically demonstrated by mortality and longevity statistics. In 1900 the life expectancy was 49 years; in 1945 it was 66 years. Thirty per cent of persons who now have attained the age of 65 owe their survival to advances in medicine and public health administration made since they were born.[3] In addition to saving more and more lives, the application of medical discoveries, since 1900, has added four years to the life expectancy of those who are now 40 years of age, and one and a half years to the life expectancy of those who are now 65 years of age. (In 1945 the life expectancy of men at 65 was twelve and four-tenths years and of women fourteen and a quarter years.) Medical progress has not only saved more lives but it has added a few years to the average life. However, the added years are probably derived more from the control of infectious disease than from the control of degenerative disease.

While many have been reaping the harvest of the achievements of medical science, public health administration and pharmaceutic chemistry, a change has been occurring in the structure of the population and in the need for emphasis on a new area of medical research. As a result of a decrease in birth rate (12.1 in 1900 and 8.3 in 1940), a decrease in immigration and an increase in persons surviving into middle and old age, the population has been shifting from youth to middle age. Almost 29 per cent of the population in this country are over 45 years of age; by 1960, 33 per cent will be over 45 years of age; 7.7 per cent, or almost 11,000,000 persons, in this country are now over 65 years of age, and by 1960, 9 per cent of the population will be over 65 years of age. This shift in population will probably occur more rapidly than is now predictable, because the mortality from pneumonia, tuberculosis and other infectious diseases is rapidly decreasing. This means that the emphasis in medical research will have to be changed and the public health program will have to be broadened.

I believe that this is a turning point in the history of medical research. The emphasis in the past, and properly so, has been on the control of the acute diseases, which, except for the virus diseases, have largely been brought under control. In the future, the emphasis must be on the chronic and degenerative diseases. The importance and urgency of this situation may be illustrated by presenting some evidence. For example, chronic cardiac disease, *cancerous arteriosclerosis, cerebral hemorrhage,* chronic nephritis and diabetes mellitus now rank among the first ten causes of death and account for 60 per cent of deaths in the United States. More dramatically, one half of the babies born in 1940 will die of degenerative disease of the circulatory system and kidneys. Moreover, middle and old age are characterized by a high incidence of disabling disease. Seventy per cent of persons now permanently disabled are 45 years or more of age. Thirty per cent of the patients admitted to mental hospitals are 60 years of age or more, most of which patients have senile psychosis due to cerebral arteriosclerosis. Six million and eight hundred thousand persons have rheumatism, and of these 1,500,000 have the degenerative form of arthritis, namely, hypertrophic osteoarthritis. One hundred and fifty thousand persons are now invalided by their rheumatic condition.

It seems clear that unless medical research discovers a way to decrease the disabilities incident to chronic illness and incapacitation of middle and old age, economy and medical practice, as it is known today, will undergo much change. The total number of sick persons will obviously increase, because of the long periods of disability. This will increase the need for physicians and nurses and for beds for hospital and custodial care. The total cost of medical care will be increased beyond that anticipated by an increase in population alone. These rather obvious facts show that since the turn of the century medical advances have been creating an obligation for future generations to care for proportionately many more old and disabled persons than are now being cared for. The only way this obligation can be lightened is by the expenditure of more money and time on research on *degenerative disease.*

Therefore, it seems clear that "to prolong useful life" is the next important contribution to be made by medicine and pharmaceutic chemistry. One of the first needs is to dispel the fatalism which surrounds the subject of degenerative disease, a fatalism which is based on a failure to learn and recognize the implications of knowledge now available. Within the last twenty years unequivocal progress has been made in the treatment of cancer, and there are reasons to believe that arterial disease may be brought under control. For instance, let me illustrate by using arteriosclerosis as an example, since it is the major degenerative disease responsible for the failure of the function of such vital organs as the heart, kidneys and brain. The following facts establish the view that something can be done about arteriosclerosis. *(a)* All persons over 80 years of age do not have decided arteriosclerosis when they die. Groddeck,[4] in autopsies of 283 persons over 80 years of age, observed that 34 per cent had only slight sclerosis of the coronaries and 3 per cent had only minimal sclerosis of the aorta. *(b)* Arteriosclerosis does not appear with equal frequency in the sexes, which is particularly true of coronary disease. *(c)* Coronary disease is more common in white persons than in Negroes.[5] *(d)* Arteriosclerosis is not uniformly distributed throughout the vascular system. *(e)* It occurs in association with renal disease and infections in children; hence it is not solely correlated with age. *(f)* It can be produced experimentally in animals by many different procedures, and its development may be modified by various drugs and procedures.[6] Numerous pathologists likewise express the belief that arteriosclerosis, such as effects the intima of arteries, is a disease and not the direct result of involution associated with aging.[7] The incidence of the disease is low in Iceland,[8] which is attributed to the high intake of iodine in food. Because of the relative complexity of the problem of the degenerative diseases and the time factor involved, the solution of this problem will be more difficult and expensive than the solution of problems presented by infectious and acute diseases.

---

SUMMARY

Progress has been made in the drug therapy of degenerative diseases, but it has been small in relation to the importance of the subject. The remarkable success which has attended the discovery of the cause, prevention and treatment of infectious and acute diseases has dramatically increased the need for the solution of the problem of the treatment of degenerative diseases. As a result of saving more lives in youth, the population has shifted from youth to middle and old age. This is a turning point in the history of medical research; the emphasis from now on will be on chronic illness and degenerative diseases. Unless something is done to prevent it, one half of the babies born in 1940 will die of degenerative disease of the circulatory system and kidneys. The achievements of the past two or three generations have rendered it necessary for future generations to care for many more old and disabled persons than are now being cared for. The next important contribution to be made by medicine and pharmaceutic chemistry is to prolong the period of useful life. There is plenty of evidence to show that cancer and degenerative diseases, such as arteriosclerosis, can be brought under control. However, the problem is more complex and its solution will require more man-hours and money than will that of the problem of infectious diseases. A society and profession which has promoted research to save human life has the responsibility of keeping that life in health.

CHRONIC BRUCELLOSIS

Conclusions on Treatment After Ten Years

JOSEPH FRANKLIN GRIGGS, M. D.
Claremont, Calif.

Only within recent years has chronic brucellosis (undulant fever) been recognized[1] as an important cause of many common complaints of a chronic or recurrent nature. The most frequent symptoms[2] are fatigability, myalgia, arthralgia, neuralgia, headaches, light-headedness, intractable eye fatigue, sweating, thermolability, myriad digestive dysfunctions, nasal catarrh or chronic sore throat or cough, tachycardia, nervous irritability, depression, insomnia or mental torpor and various disturbances of the reproductive system, especially in the female. The commonest physical findings,[1p] when there are any, are low grade fever, slightly enlarged liver, increased redness of mucous membranes, tenderness in the right lower quadrant of the abdomen and a suggestive blood picture.[1i]

The typical history is one of long duration, varied diagnoses, unsuccessful treatment, recurrent course, aggravation of debility following pregnancy, operation or "influenza" and, finally, a conclusion that the patient must be "neurotic" or the complaints "functional" or constitutional. The well known acute phase of classic brucellosis is often not discoverable in the history at all.

It may seem incredible that such a disease could have been in the population for many generations and yet have escaped detection and recognition as a common clinical entity. The reason is probably at least fourfold: 1. The laboratory procedures which usually detect the acute form of brucellosis more often give negative results in cases of chronic brucellosis.[3] 2. The manifestations of chronic brucellosis are so varied that the disease is easily misdiagnosed as one of many other conditions which it may simulate rather well.[1j,k] 3. Organ diagnoses (cholecystitis, colitis, appendicitis, endometritis, sinusitis, arthritis) have too easily satisfied diagnosticians and surgeons. Brucella is capable of affecting any and every tissue of the body[1k]; and, while it is true that foci of uncontrolled brucellar infection or secondary infection often monopolize the clinical picture, the organism is rarely confined to any one organ. Often it is only after the necessary extirpation of the focus that it becomes clear that the patient is still sick with a generalized low grade infection. 4. Man and Brucella have probably been living together since the early herdsman stage of civilization. There has been a close adaptation between the two, so that the human organism reacts but little to this invader, and the latter seldom destroys its host. The task of detecting or excluding brucellosis has presented a serious challenge to diagnostic research. This problem has been considered in previous publications.[1n,p] The development of an adequate therapy for brucellosis is a difficulty of equal magnitude.

EXPERIENCE WITH TREATMENT

The purpose of this paper is to summarize my experience with treatment in 300 cases of chronic brucellosis, chiefly in California, since 1937. The

---

Owing to lack of space, the footnotes have been omitted from THE JOURNAL but will appear in the author's reprints.

diagnosis in these cases has been reported elsewhere.[1p] I began treating with a commercial heat-killed vaccine (Brucella abortus and Brucella suis) and "brucellin" (a preparation from pooled cultures of three species of Brucella),[4] in doses recommended in the folders which accompany the products. The objective seemed to be to give the patient a fairly severe local and general reaction, to jolt his resistive processes to a high point. Sometimes the results were gratifying and successful. More often the beneficial results were short lived or quite inconclusive. A common statement by the patient was: "I can't tell whether it is the vaccine that makes me feel worse or better, or whether it is just the natural ups and downs of my disease." In at least 25 per cent of patients the large doses of commercial vaccine caused severe exacerbations of symptoms without being followed by commensurate improvement. The muscles, skin and subcutaneous tissues of these patients became more and more intolerant of brucella vaccine. Large nodular indurations formed at the sites of injection and lasted many weeks. Some of these broke down into sterile abscesses a few months later. Others showed delayed healing of the needle wounds in the skin because of slight necrosis along the path of the needle tract. These hypersensitive patients became more sensitized with the large doses of commercial vaccine, and they could not, and would not, withstand such treatment. In spite of the high opsonin and agglutinin levels which developed, they felt worse, or no better, even after treatment was discontinued.

Summary of Early Experience.—In summary, then, I found that the usually recommended doses of commercial heat-killed brucella vaccine were not advisable as a general rule, for the following reasons:

1. *(a)* Only 60 per cent of patients with chronic brucellosis so treated were benefited at all by the treatment; *(b)* many of these relapsed later; *(c)* most of them objected to the discomfort and disability of this protein shock therapy.

2. Over 25 per cent of the patients with chronic brucellosis in California manifested hypersensitivity to brucella vaccine with this method. In practical terms, hypersensitivity means local tissue intolerance to vaccine, generalized exacerbation of symptoms and a short-lived increase in agglutinins and opsonins, which is deceptive.

From this study it appeared that agglutinins and opsonins may result from hypersensitivity or sensitization as well as from immunity. If the vaccine stimulated the production of immune bodies, the good effect was counteracted by the development of hypersensitivity at the same time. This offers an understanding of patients who are not well in spite of attaining laboratory evidence of immunologic response to infection. Although the blood may show agglutinins, opsonins and complement-fixing bodies, this immunity does not necessarily extend to the preferred habitat of the brucella, which is intracellular.[5] The invader, therefore, is often well protected from blood-borne antibodies and antibiotics.

Effect of Smaller Doses of Vaccine.—The next logical step was to decrease the size of doses of the vaccine in order to avoid excessive reactions. Two methods were used. The total quantity of material injected was kept very small, 0.01 to 0.40 cc., and the vaccine was diluted with sterile isotonic solution of sodium chloride to make weaker concentrations. Each local reaction was carefully noted as to size, redness, tenderness, hardness and duration. The intervals between injections were adjusted experimentally. After an interval of five days there often appeared an increased sensitivity to subsequent injections. It was found that the concentration of the vaccine was more important than the mass volume of the injection.

The results of diluting the vaccine to a few hundred or a few thousand killed bacteria per dose were distinctly better than the results of shock dose therapy. Patients felt less abused during treatment and were less inclined to give up vaccine therapy. A larger number (75 to 80 per cent) were significantly improved. Undulations of the disease were less frequent and severe. A larger number of patients received dramatic relief from discomfort and disability. Sterile abscesses and cutaneous necrosis became unusual, or even rare. Opsonins and agglutinins appeared more gradually. However, there were still 20 per cent of patients who could not tolerate these injections of killed bacteria in any dose and a large percentage in whom the doses could not be increased without increasing sensitivity. There were also a number of patients who still felt sick in spite of good local tissue tolerance to the vaccine and good opsonic response. Theoretically, they should have been getting better, but they had reached a plateau after their initial improvement. They remained better, not very sick, but making no progress, and certainly far from cured.

Following a suggestion of Harris,[1k] I attempted desensitization with intravenous injections of vaccine in doses of a few killed bacteria, the amount being increased gradually to several thousand per dose. With only 1 or 2 patients was this successful. The hypersensitive patients continued to become still more sensitized. The doses had to be decreased instead of increased in order to avoid successively severer general reactions and persisting exacerbations. I was unable to confirm Harris' impression that after a few intravenous injections the subcutaneous route could be resumed. However, the intravenous route became valuable in a small, important group of cases after I learned what doses to use.

Effect of Nonspecific Measures.—A number of physicians have discontinued brucella vaccine therapy entirely and have fallen back on general tonic measures. From my early experience, outlined in the preceding section, it is easy to see how one could become discouraged by the bizarre results of specific vaccine therapy of chronic brucellosis. Penicillin is useless in treatment of this disease.[1r] Sulfonamide compounds have also been disappointing [6] with few significant exceptions.[7] Streptomycin does not offer much hope when given in ordinary doses.[8] Streptomycin and sulfonamide compounds,[7c] like many other agents, may appear to cause remission in the acute form of undulant fever in which sudden remission usually occurs spontaneously. In cases of the chronic form of the disease the failure of these blood-borne drugs is probably due to the intracellular existence of brucellas in the tissues.[5]

In order to test the effect of general tonic measures, I reviewed the literature and tried a number of recommended measures, without vaccine therapy. Crude liver extract; cacodylates (dimethyl arsenate); strychnine; vitamins; thyroid and other endocrine substances, as possibly indicated; salicylates, given intravenously; nitromersol N.F. ("metaphen"); congo red; iodides; colchicine, and numerous symptomatic remedies were used. As a group, patients with brucellosis did not do well on general tonic measures. Such patients feel that they need rest, but no amount of rest proves sufficient to overcome the disease in adults. The same is true of physical therapy. Almost every patient in my series had tried large doses of preparations of the vitamin B complex before coming to me. I concluded that general tonic measures are usually a discouraging waste of time, money and effort except for short periods of preparation for vaccine therapy. While waiting for the healing of necrotic lesions resulting from cutaneous tests or for the absorption of nodular reactions to vaccine, I give crude liver extract and adrenal cortex extract intramuscularly alternating with intravenous administration of vitamin B complex and a strychnine-cacodylate preparation. Only 2 patients of the 300 have improved so much on this regimen that they do not appear to need vaccine. However, both these patients have relapses when treatment is stopped for a long period.

Extreme Degrees of Hypersensitivity.—My next effort was to answer the question: How much must brucella vaccine be diluted before it can be tolerated by the most hypersensitive patients? Controlled experiments proved repeatedly that even 1 bacterium was too much for most of them! The vaccine is a solution of the specific substances, presumably proteins, of the brucella bacterium, an encapsulated coccoid bacillus, 2 to 3 microns long and about 2 microns wide. By further diluting the vaccine with saline solution and injecting it into patients, along with plain saline solution controls, I found that the sensitized human organism reacts to infinitesimal fractions of the specific substances of this microscopic pathogen. The soreness of the muscle, the redness of the skin and the induration of the tissues at the site of injection of the vaccine offer both objective and subjective proof that the dilution of the vaccine contains something not present in the diluent saline solution alone. When given intravenously, these dilutions of vaccine will produce in sensitized patients a mild to pronounced exacerbation of generalized aching, chills and fever, appearing in four to six hours and subsiding in another four to forty-eight hours.

To date, my colleagues and I have been unable to find a concentration of brucella vaccine so dilute that it fails to produce an objective reaction in the most sensitive patients with chronic brucellosis. Attempts to find such dilutions have taken us beyond the point where large protein molecules could be expected to be present, e.g., doses smaller than 1 bacterium $\times 10^{-14}$. Some specific brucella substances are polysaccharides, much smaller molecules than proteins.[9] These might explain the activity of the slightly weaker dilutions. Practically, it seems almost impossible to dilute these specific substances out of existence. Adsorption and fragmentation of specific molecules have been suggested in partial explanation of this apparent conflict with theory. By drastic cleaning technics, all known errors of adsorption have been eliminated. We have been encouraged to persist in these observations because of the similarity of brucellosis to tuberculosis and the well known allergenic properties of tuberculin in extreme dilution. Theoretic implications of these observations are being subjected to further study.

The significant clinical observation is that certain patients with extreme brucellar allergy are most difficult to desensitize unless doses of molecular size are used to initiate treatment.

Advantages of Oxidized Brucella Vaccine.—The work of Calder [1h] and Hagebusch and Frei [11] led to the use of a vaccine which is modified or attenuated by oxidation with nitrous acid in order to avoid severe reactions. The oxidized brucella vaccine was developed by Foshay, of the University of Cincinnati School of Medicine. It is prepared in a manner similar to his modification [10] of tularemia vaccine, which is well tolerated and provides protection to bacteriologists working with Pasteurella tularensis. Oxidized Br. abortus vaccine has never caused a sterile abscess or cutaneous necrosis. I agree with Calder that this vaccine is superior to any other known preparation for treatment of chronic brucellosis. However, it still causes severe local and general reactions in hypersensitive patients when used in doses of appreciable numbers of killed bacteria. Sensitivity likewise increases if the doses are increased too rapidly. During the war, supplies of oxidized vaccine were short. Commercial vaccine was often substituted, in identical doses, and it was obviously less well tolerated, apparently because it was more allergenic than Foshay's oxidized vaccine.

PRESENT THERAPY

Principles.—By avoiding general reactions entirely and striving to find the minimum dose which will produce a local reaction of not more than twenty-four hours' duration, a method of treatment has been evolved which enables me to treat individually every patient with chronic brucellosis with greater satisfaction than by any other therapy in my experience. The principles of the present method are as follows:

1. One should never begin vaccine therapy until all tissue reaction to previously administered vaccine or cutaneous tests has completely subsided. Initial intradermal tests should be made with very dilute materials, such as "brucellergen" (a suspensoid of nucleo proteins of brucella cells) diluted to 1:120,000 or doses of vaccine representing no more than 1,000,000 killed bacteria [11] in 0.05 cc. Sensitivity is always increased by necrotic reactions and by indurations due to unabsorbed vaccine. Desensitization is practically impossible as long as there is a breakdown of tissues anywhere in the body as a result of living brucellas or specific brucellar derivatives (allergens).
2. Treatment should begin with vaccine diluted (and preferably modified) so that the initial doses will probably be too small to produce any general reaction and will cause only a minimal local reaction, if any. For hypersensitive patients this may mean a dose of much less than 1 killed bacterium, preferably about 1 molecule of specific antigen.
3. Injections should be made into the muscles of the thigh and deltoid region in order to avoid the variable slower rates of absorption by the subcutaneous route.

4. Another injection of vaccine should never be given while there is any induration, redness, swelling or tenderness from the previous dose. The sites should be inspected and palpated; one should not accept the patient's word that the previous reaction has subsided.

5. Injections should be given every two or three days, as reactions permit. The intervals between doses should not be more than five days by whatever route the injection is given.

6. When there is only a minimal local reaction, subsequent doses may be doubled each time until larger reactions begin to appear. Then the doses should be increased by only 0.02 to 0.10 cc. The maximum dose reached in any one concentration or dilution of vaccine is 0.45 cc. After this dose is given, the next dose is 0.05 or 0.10 cc. of a dilution ten times as concentrated.

7. If reactions become progressively severer in spite of little or no increase in doses of vaccine, the injections should be stopped for five days or more and the series begun again with a much weaker dilution of vaccine than has ever before been used for the patient. The doses are increased more gradually. A different route, such as the intradermal [12] or the intravenous one,[1k] will be necessary for some patients.

8. Vaccine therapy may be discontinued when the patient is apparently recovered symptomatically and has a high phagocytic index which has been attained gradually without sensitization. In the case of young, vigorous patients this will require several weeks. For the majority of all patients it requires more than one year. The size of the final dose attained may be only a few killed bacteria when only desensitization is required, or it may be several billion killed bacteria in an undenatured vaccine when sensitivity is low.

9. If a patient is not recovered clinically after the gradual building up to large doses and a high phagocytic index, the following measures are indicated, in the order designated:

(a) Desensitize again, even though the patient's tissues do not appear to be hypersensitive.

(b) Search again for foci of infection, usually mixed, and give appropriate treatment with surgical measures or short wave diathermy, roentgen irradiation and medication, along with the vaccine. Investigate again the diagnosis as a whole.

(c) Repeat the desensitizing-immunizing series of injections with a vaccine of different strains of brucella, preferably from the geographic area where the patient contracted the disease.

(d) Try larger doses and greater concentrations of vaccine.

(e) Discontinue vaccine for an observation period of several months.

(f) Repeat the series, using a different route, either intradermal or intravenous, and increase the doses more gradually.

Additional Points of Treatment.—Dilutions of vaccine must be made with extreme accuracy and care to prevent contamination. We use 0.2 per cent phenol in the diluent. Dilutions should be kept fresh and cold and should be cultured periodically. The concentration of vaccine in the dilutions is seriously disturbed if a needle which has entered a strong dilution is used to prepare or administer weaker dilutions. Syringes are thoroughly cleansed after each use with detergents, soaked overnight in a concentrated solution of sulfuric acid and potassium bichromate and thoroughly rinsed before sterilizing. Needles are cleaned with detergents and soaked in 1 per cent sodium hydroxide-alcohol solution for one-half hour after each use, then rinsed well and sterilized. Sterilization is done by autoclaving or with dry heat, not by boiling in a common water bath. The supply of sterile isotonic solution of sodium chloride used for making dilutions and for cutaneous test controls must be rigorously protected from contamination with any needle, syringe, bottle or rubber stopper which might have even the minutest amount of brucella vaccine adhering to it. Failure to observe these precautions will result in inaccurate doses and erroneous conclusions.

Patients should be warned that they will continue to experience some of the natural undulations of their disease even while they are under treatment. They should be ordered to resume normal activity to the limit of their will power, short of exhaustion. Sedatives and nearly all other medications are to be discontinued within a few days or weeks after vaccine therapy is started. Most patients on special diets for "ulcer" and "colitis" can usually resume normal, adequate eating habits. A very few patients, until they are desensitized, may need to avoid milk and milk products, beef and pork which contain brucella substances to which they are allergic. Vacations from vaccine should be firmly discouraged because of the possible increase in sensitivity after five days. Intelligent patients can be taught in a few weeks to administer the vaccine to themselves, checking with the physician once or twice a month. Gratifying improvement is usually noticed within two months of beginning treatment.

SUMMARY AND CONCLUSIONS

The difficulties in treating chronic brucellosis are examined.

Ten years' experience in the treatment of 300 patients by various schemes of specific vaccine therapy is reviewed. The usual methods of using brucella vaccine have been rather disappointing. Nevertheless, vaccine administered by an improved method appears to offer better results than any other management.

The chief obstacle to vaccine therapy was found to be the patient's sensitization to brucella substances. This hypersensitivity reached an extreme degree in about 25 per cent of cases in California.

A safe and effective method of treating chronic brucellosis with oxidized brucella vaccine has been developed and is reported in this paper. The principles involve desensitization with ultraminute fractions of oxidized brucellas before or after using larger doses.

Advantages of this therapy are that *(a)* it is applicable to nearly all cases of chronic brucellosis; *(b)* it is usually accompanied with symptomatic improvement instead of unpleasant reactions; *(c)* it is economical financially; and *(d)* it produces improvement, remissions or recoveries in 85 to 90 per cent of all cases.[13]

Disadvantages are that *(a)* a long time is required to complete the treatment in most cases; *(b)* old persons and those with foci of infection and severe hypersensitivity are often difficult to treat, requiring much time, patience and interest on the part of both patient and physician, and *(c)* the vaccine should be specially prepared and requires meticulous care in diluting and handling. Permanence of remission or cure cannot be promised to patients because our experience with chronic brucellosis has been of too few years' duration.

Brucellosis is not a self-limited disease. In the chronic stage, it shows little or no tendency to spontaneous recovery in adult life. Treatment, even at best, is difficult and uncertain in effect. However, specific vaccine therapy, modified as reported here, offers a significant advance in the treatment and prognosis of chronic brucellosis.

RECENT PROGRESS IN NUTRITION AND ITS RELATION TO DRUG THERAPY

C. A. ELVEHJEM, PH. D.
Madison, Wis.

The "Corpus" of Hippocrates not only lists many drugs, mainly of vegetable origin, but gives considerable space to a discussion of the regulation of the diet. However during the evolution of medical treatment much greater emphasis has been placed on drugs than on nutrition. This is not surprising, since as man sought food to satisfy his hunger he encountered a variety of substances which had a more or less immediate effect on the normal functions of the body. Many of these were prepared or concentrated so that they could be used to alleviate suffering or to combat disease.

The recognition of specific nutrients in the prevention of disease was impossible until a little over a hundred years ago because until that time all foods were assumed to supply a single universal nutrient. It is only within recent years that all the nutrients necessary for optimum nutrition have begun to be recognized and identified. Furthermore, druglike materials usually have an immediate effect, while the omission of an essential nutrient from the diet produces a deficiency only after a considerable lapse of time. Thus certain substances have been used variously as a therapeutic agent and as a source of an essential nutrient. One of the best examples is cod liver oil. Cod liver oil was recommended by the English physician Howel for the treatment of wounds as early as the fifteenth century. By 1730, Norwegian fishermen associated its use with the prevention of rickets. However, there was no explanation for its effect in either instance, and the scientific world hesitated to acknowledge its use. In 1837 cod liver oil was found to be a rich source of iodine, and on this basis it was entered in the pharmacopeia. However when other sources of iodine were found to be equally as effective its use fell into disrepute and cod liver oil was considered to have no greater value than other fats. In spite of this, people continued to use it and the pharmacists continued to keep it in stock. Sound basis for its use came only after careful animal experimentation had shown that cod liver oil would prevent both vitamin A and vitamin D deficiencies. Today cod liver oil is accurately standardized on the basis of its vitamin A and vitamin D content. In other words, if a vitamin or nutrient is to exhibit a pharmacologic action it must be used under specific pathologic conditions.

In spite of the greater emphasis on drugs, there has always been a close association between nutrition and drug therapy. Legislative control was combined in the Federal Food and Drug Act of 1906 and in the Federal Food, Drug and Cosmetic Act of 1938. The Council on Pharmacy and Chemistry of the American Medical Association, established in 1905, gave such considerable attention to foods that a Committee on Foods was established in 1929, which later became the Council on Foods and Nutrition. Increased knowledge of physiology has done much to give an insight into the mechanisms of the action of drugs on tissues and organs. Studies in nutrition have led to a greater degree of specificity in the use of drugs and have given a basis for the development of new specific therapeutic agents.

These relationships have been numerous, but I shall limit my discussion to those in three areas, namely, antianemic substances, amino acids and metabolic antagonists.

ANTIANEMIC SUBSTANCES

Iron therapy in anemia probably dates back to 1746, when Menghinis demonstrated the presence of iron in blood and claimed that the iron content could be increased by a diet rich in this element. However it was not until about 1830 that evidence was presented to show that the blood of chlorotic patients was low in iron and that the administration of iron increased the number of red blood cells. These observations gave rise to a large number of iron preparations for the treatment of anemia. These included insoluble forms, colloidal forms and ferric and ferrous forms. Many of these were widely used, but there was no agreement as to the efficacy of iron preparations in the treatment of simple anemia until 1928, when it was clearly established from animal studies that inorganic iron in the presence of copper is readily utilized for the synthesis of hemoglobin. Furthermore, it was shown that simple iron salts which are easily ionized are more readily utilized by the body than complex forms such as hemoglobin. It was also possible to obtain a rather definite answer concerning the relative value of ferric and ferrous forms of this element. This work clarified the knowledge regarding simple hypochromic anemia, allowed the preparation of standard forms of iron and also demonstrated that anemias which do not respond to an adequate supply of iron and copper must be due to the lack of other nutrients. Anemia due to iron deficiency was recognized as a secondary or nutritional anemia, but the so-called pernicious anemia was considered to be far removed from the state of nutrition. Pernicious or primary anemia, first described by Addison in 1849, differed from secondary anemia in the absence of a recognized cause and in the failure to respond to forms of treatment effective in other forms of the disease. In 1926-1927 Minot and Murphy reported that a number of patients suffering from pernicious anemia responded to the daily administration of 250 to 500 Gm. of mammalian liver. This immediately placed liver in the field of drug therapy, and I suppose that the reason liver had not been used previously was because it was

---

Read before the Scientific Award Ceremony of the American Pharmaceutical Manufacturers' Association in honor of the American Medical Association, New York, Dec. 16, 1947.

needed in such large quantities. Anti-pernicious-anemia concentrates were prepared in large volume by many pharmaceutical companies. Great difficulty was encountered in standardizing the products because in the absence of animal assays it was necessary to test all the preparations on human subjects. Even so, excellent concentrates were manufactured, and these preparations were standardized and accepted in the "United States Pharmacopeia."

It is not surprising that pernicious anemia was not produced in experimental animals when only a few of the vitamins were recognized. In order to keep the animals alive long enough for changes in the blood to occur it was necessary to add several crude concentrates, and these could easily carry unknown factors. However, as each new member of the vitamin B complex became available in pure form, workers had a new hope that a pernicious-anemia-like condition might be produced. Each new attempt ended in failure, and finally it was found that rats could be maintained for long periods with no evidence of anemia on highly purified rations in which all the B vitamins were supplied in synthetic form. If a pernicious anemia factor or an extrinsic factor were required by this animal, where was the required supply obtained? It was only through the use of the newly discovered sulfonamide drugs that additional deficiencies were produced in the rat. When sulfaguanidine was added to the basal ration of a young rat, growth retardation resulted, and later it was found that there was a constant development of leukopenia and agranulocytosis. The condition was prevented with whole liver and with many liver extracts known to be rich in the anti-pernicious-anemia factor. But the anemia was not severe, and it was not a characteristic macrocytic anemia. Today it is known that the addition of the sulfonamide drugs decreased the synthesis of folic acid and biotin by the bacteria in the intestinal tract and that the blood dyscrasias developed largely because of a folic acid deficiency. In this connection it is interesting to note that the incidence of agranulocytopenia increased from 3 per cent among patients admitted to a children's hospital before the introduction of sulfonamide medication to a maximum of 12 per cent in 1942, when the use of sulfadiazine was at its peak. Folic acid therapy has been found to be of considerable value in the treatment of these patients. Studies in the field of nutrition, therefore, developed a means of combating the secondary effect of some of the sulfonamide drugs.

The greatest progress in the development of the knowledge of folic acid came from the use of microorganisms and chicks. As early as 1939 Hogan and Parrott found that chicks placed on purified rations which were adequate for the rat grew normally when 4 per cent of a water extract of liver was used but that anemia developed when it was used at lower levels. Similar studies were in progress in the laboratory at the University of Wisconsin when Snell and Peterson were working on a factor necessary for the growth of the Lactobacillus casei, and when preparations containing the bacteria were fed to chickens receiving purified rations containing all the known vitamins, normal growth and hemoglobin formation were obtained. The use of microbiologic assays facilitated the final isolation, characterization and synthesis of folic acid, or pteroylglutamic acid, by the workers at the Parke-Davis and Lederle laboratories.

The availability of synthetic folic acid has permitted its use in addisonian anemia, in nutritional macrocytic anemia and in sprue. It is now generally recognized that its action is not complete, but I am not competent to discuss the details of the relationship in human therapy. However, I do want to emphasize that with the availability of this substance it has been possible to extend studies on animal nutrition so that further knowledge may be gained regarding other anti-anemic substances. For example, chicks fed a synthetic diet will develop normally if folic acid is supplied in addition to the other known B vitamins. However, if certain natural rations containing soy bean oil meal and corn meal are used, a retardation in growth results, which is prevented by the administration of highly purified anti-pernicious-anemia preparations. These preparations contain extremely small amounts of folic acid. Somewhat similar results are obtained in the rats, but the results are much more erratic, undoubtedly because of a greater degree of intestinal synthesis. It is important to point out that neither of these species of animals shows anemia and that the only apparent deficiency is lack of growth.

Dogs develop remarkably well on synthetic diets containing no folic acid, but by the elimination of one of the known vitamins, especially nicotinic acid, a conditioned deficiency can be produced which will also respond to highly purified pernicious anemia preparations. In this instance an anemia does develop which may be called a macrocytic anemia. I do not wish to conclude that the substance active in the dog is the classic anti-pernicious-anemia factor, but it is important to point out that these new methods give a means of measuring additional factors and that eventually the production of true pernicious-anemia-like conditions in an animal should be possible.

Furthermore, deficiencies can be produced in animals such as the monkey, the mink and the fox which do not respond to pernicious anemia preparations but do respond to the addition of whole liver or raw milk. The activity in the whole liver can be concentrated, and it now appears that there may be more than one additional factor. It is also interesting that in both the monkey and the mink certain paralytic symptoms appear which may possibly be related to the degenerative conditions seen in human pernicious anemia and which may be aggravated when pure folic acid is used rather than liver preparations. It is interesting to recall that most of the experimental work on iron and copper has been done with milk diets, and now milk has been shown to contain the additional factors needed for hemopoiesis.

At the present time folic acid has not replaced liver preparations and it cannot be said that there are clearcut methods for the assay of pernicious anemia activity, but it is evident that there is a closer approximation to a complete understanding of the syndrome.

Furthermore, pernicious anemia is undoubtedly a disease of nutritional origin, although the relationship is complicated by the indirect effect of the production and destruction of nutrients in the intestinal tract by the bacteria. So-called synthetic diets may yield a more favorable environment for organisms producing needed vitamins than the mixtures of natural foods which man relies on. Conditioned deficiencies may therefore develop which can be overcome by the addition of factors which normally do not need to be supplied preformed in the diet.

AMINO ACIDS

Proteins have been given little consideration as therapeutic agents, undoubtedly for two reasons. First, proteins must be supplied in large amounts in order to produce a significant effect, and, secondly, medical workers have for many years felt that the protein content of the diet should be decreased rather than increased. During the past few years there has been a tremendous change in this point of view, and at the present time there is much interest in increasing the intake of protein in many pathologic conditions and also a greater interest in the use of protein hydrolysates and amino acid mixtures than in the use of intact proteins. Much of this interest is undoubtedly due to the fact that nutrition workers have clearly demonstrated that a deficiency of amino acids may develop much more rapidly than a deficiency of vitamins or minerals. Knowledge in this field has accumulated because it is now possible to feed animals a diet complete in all factors except protein or amino acids and because of the improved methods for the estimation of individual amino acids. One of the problems encountered in the use of free amino acids is that of imbalance. The importance of imbalance grew out of the early work in which it was shown that the addition of 40 parts of corn to a synthetic diet containing 15 per cent protein and no nicotinic acid produced a marked retardation in the rate of growth of rats. This retardation was completely counteracted by the addition of a small amount of nicotinic acid, and later it was shown that tryptophane had the same effect. Further work has shown that other proteins low in tryptophane, such as gelatin, produce the same effect as that observed with the corn rations. In fact, if 2 per cent of an acid-hydrolyzed casein is added to a ration containing 9 per cent of casein, a notable retardation in growth occurs. This reduced growth is corrected with the use of either nicotinic acid or tryptophane. If 2 per cent of unhydrolyzed casein is used, an increased rate of growth results. The toxic effect of the acid-hydrolyzed casein is not due to any injurious substance formed during the hydrolysis since a mixture of pure amino acids compounded to be equal to 2 per cent of the acid-hydrolyzed casein produces the same effect. Apparently in the absence of tryptophane certain amino acids have a definite injurious effect when fed at increased levels and in the free form.

Further work has shown that the amino acids most active in this respect are threonine and phenylalanine. It has also been shown that the injection of threonine has the same effect as the oral administration. It is clear, therefore, that in spite of the potential possibilities in the use of amino acid combinations there is much to learn regarding the proper concentrations of the individual amino acids in these mixtures.

Can a mixture of pure amino acids completely replace proteins in a diet? The answer to this question apparently depends largely on the age of the animal used. For example, Cannon and his coworkers have used mature rats and have subjected them to a protein depletion. When these depleted animals were given a mixture of sixteen amino acids patterned after the composition of casein, the gain in weight was identical to that obtained when they were given a comparable amount of casein. In other words no evidence for the need of an accessory factor to promote the utilization of these amino acids was obtained. Woolley, working with young mice, has found that when they are given a purified ration in which the nitrogen source is a supplemented casein hydrolysate maximum growth is not obtained until certain proteins or concentrates from these proteins are added. He has shown that the activity of different proteins is similar to their strepogenin content as determined with L. casei. My colleagues and I have worked in our laboratory with weanling rats and have obtained a growth of as much as 3 Gm. per day by using a mixture of the ten essential amino acids supplemented with glutamic acid to provide a total nitrogen content equal to that supplied by 10 per cent of casein. The addition of small amounts of intact proteins at the expense of glutamic acid gave only a slight increase in the rate of growth. It appears, therefore, that if intact casein contains a growth-promoting factor for rats other than the essential amino acids then the concentration in casein is too low to satisfy the requirement. Rose has reported the existence of a growth factor for rats in casein which has properties in common with strepogenin. In the light of the work on amino acid imbalance it is apparent that each amino acid must be supplied in optimum concentration before the need for accessory peptide-containing compounds can definitely be settled. In fact the excretion of many of the amino acids in the urine is increased when proteins of poor quality are fed, which means that the amino acid pattern is not optimal for use as fed to rats and mice.

This leads to the interesting observation that has recently been made regarding the rate of liberation of different amino acids from a given protein. For example, in casein the essential amino acids seem to be liberated at a more rapid rate than the nonessential ones. Cystine seems to be liberated at an extremely slow rate. Heat treatment of different proteins also alters the rates at which the amino acids are liberated. Perhaps there is a definite pattern of liberation which will give optimum utilization of the essential amino acids and which also influences the intestinal flora in such a way as to give better nutrition. In any case the kind and the amount of amino acids as well as the rate at which they are supplied to human beings may have an important bearing not only on adequate protein intake but on total nutrition. The availability of protein hydrolysates and free amino acids will do much to facilitate studies necessary to clarify this relationship and will be useful in supplementing diets shown to be inadequate on this basis.

METABOLIC ANTAGONISTS

As I indicated earlier, the introduction of druglike materials in therapy has been dependent largely on trial and error. It is only recently that chemical constitution has been closely correlated with biologic activity. The developments in nutrition have done much to make studies possible.

In the first place, metabolic studies can be carried out only when it is possible to feed an adequate and known diet. Secondly, the availability of many of the nutrients in pure and synthetic form has allowed modification in the structure of these compounds. Out of this work has come the general recognition that slight modifications in the structure of certain vitamins may change them from essential nutrients to metabolic antagonists. A relationship of this kind was encountered in 1937, when the anti-blacktongue activity of a number of derivatives of nicotinic acid was studied. In this work it was found that 3-acetylpyridine actually aggravated the blacktongue condition in dogs. The significance of this observation was not realized until Woolley extended his studies on the biochemical antagonism. The work which attracted greatest attention was that of Woods and Fildes, who showed that para-aminobenzoic acid has antisulfonamide activity. This effect was explained on the basis that para-aminobenzoic acid is an essential nutrient and that the sulfonamide compounds functioned by interfering competitively with para-aminobenzoic acid. The discovery of this relationship prompted attempts to produce similar structural changes in other vitamins in the hope of producing other bacteriostatic compounds. The growth of certain bacteria was inhibited by 3-pyridinesulfonic acid, and the inhibition was reversed with nicotinic acid. "Pantoyltaurine" likewise produced bacteriostasis, which was reversed by pantothenic acid. Although much of the early work was done with bacteria, it was soon recognized that severe vitamin deficiencies could be produced through the use of antivitamins related to thiamine, riboflavin, vitamin K, vitamin E, biotin and other factors. Of great interest is the recent work on the use of 7-methyl folic acid in the production of a more severe anemia in experimental animals. This effect appears to be different from the action of the sulfonamide drugs which I mentioned earlier, since it is now known that para-aminobenzoic acid is a part of the folic acid molecule and that the sulfonamide drugs prevent the incorporation of para-aminobenzoic acid into the folic acid. Specific antagonists for folic acid may give the final answer to the relation of folic acid to the anti-pernicious-anemia factor.

The studies have not been limited to vitamins. Dyer has shown that ethionine is toxic for young rats maintained on a diet free from methionine and that the toxicity could be prevented by the addition of the latter. In all cases the relationship between the nutrition and the drug therapy is obvious, and I believe that future studies along this line will be most productive.

For several years we have been studying the possible relation of nutrition to resistance to virus infection, using mice and several viruses closely related to the virus of infantile paralysis. We have found that mice deficient in thiamine are almost completely resistant to paralysis produced by these viruses. In the presence of adequate thiamine the incidence of paralysis reaches approximately 100 per cent. Similar results have been obtained with riboflavin and pantothenic acid, although the differences have not been so striking. It has also been possible to increase the resistance by producing potassium and phosphorus deficiencies. Recently this work has been extended to the field of amino acids, and we find that mice deficient in tryptophane show less paralysis when infected with the virus than those receiving adequate quantities. Furthermore, a more severe tryptophane deficiency develops in infected mice than in uninoculated ones. This may indicate that the virus has a preference for certain amino acids. This is not surprising, since it is known that the virus multiplies rapidly and that it is composed largely of protein material. This logically suggests the possibility of using certain analogues of tryptophane to alter or modify the development of certain viruses. There are undoubtedly many difficulties and obstacles in a program of this kind, but even if practical applications do not come out of this work much fundamental knowledge must accumulate.

In conclusion it may be said that from the point of view of drug therapy a compound having positive nutritional effects should theoretically disappear from the list of useful drugs. If the compound is known and its content in foods can be estimated, the corresponding deficiency should be prevented through the use of natural or fortified food and the deficiency should never appear. However, from past experience it is obvious that optimum nutrition for all will never be obtained and that there will always be need for these specific compounds for clinical use. The main objection to the use of pure substances in nutritional deficiencies is the fact that unknown factors may be ignored. That is why for several years vitamin B complex preparations always contained some natural sources of nutrients. The availability of synthetic folic acid apparently does not completely eliminate this necessity, and it may be some time before the natural sources can completely be ignored.

Studies on the development of compounds having a negative nutritional effect are in their infancy, and it is impossible to predict the extent to which these compounds may eventually be used in the treatment of infectious diseases. Nevertheless it is apparent that the search for new agents for use in human therapy will in the future be based largely on studies with animals and micro-organisms. Work in the field of nutrition has done much to establish the metabolic similarity between all living cells, which is the basis for this new type of approach.

TUBULO-VASCULAR SYNDROME—Renal vasconstriction is a rather general reaction occurring whenever the efficiency or integrity of the circulation is threatened by cardiac injury or disease, skeletal trauma, hemorrhage, dehydration, and comas. Presumably, the immediate effect of this diversion of blood from the kidney is to make more of the low cardiac output available to vital areas—heart, brain, lungs, liver. So far so good. A few hours of oliguria or even anuria is not a catastrophe; and it is a fact that the kidney can safely stand complete interruption of its arterial blood supply for 20 or 30 minutes. But when the state of renal vasoconstriction and marked ischemia persists for 12 to 24 hours or longer, something apparently happens to the vitality of the tubular epithelium and a whole series of dysfunctions arise, with or without structural alterations, that may lead irreversibly to uremia and death even though the original injury to the body or to the circulation may already have been corrected. . . . Leiter, Louis, M.D., Renal Diseases: Some Facts and Problems; Annals of Internal Medicine, February 1948, Vol. 28:241.

GONOCOCCIC MENINGITIS FIFTEEN YEARS AFTER URETHRITIS

STEPHEN L. STIGLER, M.D.
and
JAMES S. McLESTER, M.D.
Birmingham, Ala.

Gonococcic meningitis is looked on as a rare disease. In many text books it is not even included among the complications of gonorrhea. The first mention of it was possibly in 1805, when nervous manifestations were described in conjunction with gonorrhea.[1] It was not until 1879 that the gonococcus was discovered, and not until 1905[2] that positive means of identification, such as the differential sugar reactions and the agglutination, agglutinin absorption and complement fixation tests, were introduced. In 1909 the review of the literature of this malady by Henderson and Ritchie[1] closed the era of purely clinical diagnosis and opened a new era of laboratory confirmation.

What then are the criteria necessary to establish the identity of the gonococcus? Birkhaug and Parlow[3] have stated that in addition to the morphologic and cultural characteristics of this organism, the only reliable criterion is either its fermentation of dextrose or one of its serologic reactions, such as agglutination, agglutinin absorption or complement fixation. Branham, Mitchell and Brainin[4] have rated the dependability of the laboratory procedures for the identification of the gonococcus as follows: 1. The cultural features and the type of colony are the most fundamental and typical differences. The gonococcus produces a delicate growth on blood agar, with small translucent convex colonies. 2. The fermentation of various sugars is typical in that dextrose is readily fermented but no other sugar is so affected. 3. The alkali solubility test is of value but is not an absolute criterion. In the test of Thomson as described by Pelouze[5] the gonococcus is, as a rule, instantly and completely dissolved, leaving a completely clear solution. Meningococci are partially dissolved, but the stroma remains, leaving an opalescent fluid. Micro-organisms such as streptococci and staphylococci are untouched in the dilution of alkali used. 4. Serologic methods of differentiation have not been satisfactory, as gonococci are often agglutinated by polyvalent antimeningococcus serum as well as by antigonococcus serum. Nearly all gonococci are agglutinated more strongly by type II antimeningococcus serum than by the other type serums, although some show considerable cross agglutination.

Since all cases of gonococcic meningitis prior to 1905 were diagnosed without benefit of laboratory confirmation, this date may reasonably be used as a starting point for any present day review of this disease. Since that time 40 cases have been reported. In some of these instances adequate proof of the diagnosis is lacking, and therefore these cases must be considered merely as possibly or probably gonococcic in origin. Such reports would include those of Wynn,[6] Prochaska,[7] Bieck,[8] Romback,[9] Henderson and Ritchie,[1] Morelli[10] and Lindenfeld.[11] There remain 24 patients,[12] including the present one, in regard to whom the diagnosis can be considered to have been adequately established.

Gonococcic meningitis occurs more commonly in young male adults and, as a rule, it is secondary to a genital infection. All age groups have been involved, including a newborn infant.[2] Branham and associates[4] reported 2 cases of simple, uncomplicated primary gonococcic meningitis without any recognizable focus of infection, and as far as could be determined, no known opportunity for infection. It is interesting that our patient had experienced no gross recurrence of his primary gonorrheal urethritis in fifteen years, yet his meningitis apparently originated from an old focus in the prostate gland.

The signs and symptoms of gonococcic meningitis are apparently indistinguishable from those of meningococcic meningitis; the presence of gonorrhea or a suggestive history often indicates the true nature of the disorder. From the point of view of the pathologist the two diseases are grossly similar. In several instances gonococcic meningitis appeared in the presence of gonorrheal arthritis.

Marvin and Wilkinson[12i] in their review of the literature in 1938 told of a mortality of 45 per cent; they reported the first case in which the patient was treated with a sulfanilamide. Undoubtedly with the present day use of penicillin and the sulfonamide compounds, the mortality rate should decline markedly.

Five hundred cultures of blood and spinal fluid were made by Branham and associates[4] in a search for the meningococcus, and 10 (2 per cent) were found to contain gonococci. Subsequently these authors reported 3 additional cases. This leads one to suspect that gonococcic meningitis is more frequent than is commonly believed.

REPORT OF A CASE

C. M., a white man aged 35, was admitted to the hospital on June 3, 1946 because of nausea and vomiting of three days' duration. He had been well until three days prior to admission, when he became dizzy and nauseated and had fever. Shortly thereafter he experienced chilliness, generalized muscular cramping, malaise and a severe frontal headache. Stiffness of the neck then appeared. All symptoms

became more severe on the day of admission. The vomitus now became dark brown, and there was severe epigastric pain. Red spots appeared on his skin; these were generalized in distribution and were not accompanied by itching or other discomfort. His past history disclosed that he had contracted gonococcic urethritis at the age of 20 years and that following treatment there had been no recurrence. Since this infection, however, he had suffered occasional slight dysuria.

The patient was a thin white man who appeared to be acutely ill. The blood pressure was normal in both arms, and the temperature was normal. The pulse rate was 94 and the respirations 22 per minute. Petechiae, varying from bright red to brown, were present in the skin and the mucous membranes. No abnormalities of heart or lungs were found. Some generalized tenderness of the abdomen was noted, but no masses were felt. Examination of the genitalia and the rectum did not reveal any abnormalities. Opisthotonos was present, and flexion of the neck caused marked pain. A Brudzinski sign was observed. The deep reflexes were hyperactive on both sides, and there was a bilateral Kernig sign.

A lumbar puncture brought cloudy fluid, which exerted a pressure of 230 mm. of water. About 15 cc. of fluid was withdrawn, and in its place was injected 10,000 units of penicillin in 10 cc. of isotonic solution of sodium chloride. The spinal fluid showed 94,000 white cells per cubic millimeter, all of which were polymorphonuclear leukocytes. Smears of the fluid showed gram-negative intracellular diplococci. The total protein was 1.93 Gm. per hundred cubic centimeters. The sugar was less than 20 mg. per hundred cubic centimeters. The globulin was 4 plus. The Wassermann reaction was negative. The colloidal gold curve was 1355555555.

The urine on admission was normal except for the presence of albumin. The blood count on admission showed red cells 4,610,000, white cells 27,300, hemoglobin 90 per cent; the differential cell count showed 92 segmented forms and 8 lymphocytes. The Wassermann test was negative.

Because the persistent vomiting prevented adequate oral medication, 5 Gm. of sodium sulfadiazine was given intravenously in 1,000 cc. of an isotonic solution of sodium chloride containing dextrose in a concentration of 5 per cent. Fifty thousand units of penicillin was given intramuscularly, and subsequent injections of 30,000 units each were given every three hours. After the initial intravenous dose of sodium sulfadiazine, the patient was given orally 2 Gm. of sulfadiazine every four hours, to which was added an equal amount of sodium bicarbonate. Suitable supportive measures were also applied. Two days after admission the blood sulfadiazine level was 14.2 mg. per hundred cubic centimeters.

The patient remained afebrile and improved rapidly. Three days after admission, a second lumbar puncture was done, and an initial pressure of 290 mm. of water was observed. The slightly cloudy fluid was slowly removed until the pressure reached 100 mm. of water, at which time 15,000 units of penicillin was injected intrathecally. Examination of this fluid revealed 850 white cells per cubic millimeter, all of which were polymorphonuclear leukocytes. No organisms were seen on smears, and no growth appeared on the cultures. The sulfadiazine level of the spinal fluid was 6.5 mg. per hundred cubic centimeters. The use of this drug was stopped on the twelfth day, after a total of 133 Gm. had been administered. The use of penicillin was discontinued after 1,000,000 units had been administered. Recovery was uneventful, and apparently there were no residual effects.

Prostatic fluid obtained at this time by massage revealed extracellular gram-negative diplococci, but no organisms were obtained from cultures. This is not surprising, however, in view of the medication to which the patient had been subjected.

Because of the hematemesis and epigastric pain during the early part of the illness, appropriate roentgenograms were made. These did not reveal any abnormality of esophagus, stomach or duodenum.

The organism grown from the spinal fluid obtained at the first lumbar puncture was identified as the gonococcus. A blood agar plate was inoculated with fresh spinal fluid and incubated aerobically. A chocolate agar plate was inoculated with fresh spinal fluid and incubated in 10 per cent carbon dioxide. After twenty-four hours the blood agar plate showed no growth, and the chocolate agar plate revealed small, dewdrop-like colonies, which were found to be gram-negative diplococci. Maltose, sucrose and dextrose were inoculated with these organisms, and dextrose was the only sugar fermented after forty-eight hours under carbon dioxide. Several attempts to agglutinate the organism with types I, II, III and IV antimeningococcus serums were unsuccessful. A fresh culture of the organism was grown on chocolate agar in 10 per cent carbon dioxide, and the culture was then flooded with 10 per cent dimethyl-para-phenylenediamine hydrochloride. The colonies gave a positive oxidase reaction, turning pink and then black. These tests confirmed the diagnosis of gonococcic meningitis.

SUMMARY

Twenty-four cases of proved gonococcic meningitis are found described in medical literature, but it is probable that the disease occurs more frequently than this figure would indicate.

The disease occurs chiefly in young male adults of both the white and the Negro race, and is generally secondary to gonorrheal urethritis.

The criteria for the positive identification of gonococcus are presented.

A case of gonococcic meningitis, probably secondary to chronic *gonococcic prostatitis, is reported.*

CLINICAL EVALUATION OF THE ANALGESIC METHADON

ELIZABETH B. TROXIL, M. D.
Minneapolis

A new synthetic analgesic, originally prepared by German chemists and known as drug 10820, was made available to this country following World War II. The original report was published by the U. S. Department of Commerce.[1] The Council on Pharmacy and Chemistry of the American Medical Association has given this compound the nonproprietary name of methadon.[2]

The compound is a white crystalline substance soluble in water and alcohol, but insoluble in ether, having the following formula: 6-dimethylamino-4,4-diphenyl-3-heptanone hydrochloride. The compound contains an asymmetric carbon atom and is supplied as the racemic mixture. It is quite possible that the *d*- and *l*- isomers may have different degrees of activity.

From the Department of Pharmacology, University of Minnesota Medical School.

[2] Smith, A. E.: Personal communication to the author.

A pharmacologic investigation was undertaken by Scott and Chen,[3] who reported that the drug had some of the characteristics of both morphine and meperidine hydrochloride ("demerol hydrochloride" N.N.R.) in animals. The effects on the nervous, circulatory and respiratory systems, as well as the side effects, were similar to those of morphine. Action on the intestinal tract consisted of a morphine-like short period of spasm followed by an antispasmodic effect equal to that produced by meperidine hydrochloride. No tolerance or addiction to the drug was found. Determination of the pain threshold by the Wolff-Hardy technic indicated that, weight for weight, methadon was a more potent analgesic than either morphine or meperidine.

Woods, Wyngaarden and Seevers[4] have studied the addiction potentialities in rhesus monkeys and have found that physical dependence and withdrawal symptoms do not occur after chronic administration of methadon. They also found no tolerance to the drug but rather an increased susceptibility.

Recent investigations have been carried out by Isbell, Wikler and co-workers,[5] who found that 2.5 mg. of methadon given subcutaneously raised the pain threshold (Wolff-Hardy technic) as much as 10 mg. of morphine. Doses of 5 mg. of methadon produced little or no effect on temperature, pulse rate, blood pressure and respiratory rate in man. Larger doses slowed the pulse and lowered the blood pressure. Doses of 20 to 30 mg. of the drug always produced narcosis and sedation. They[6] also observed the effects of methadon in former morphine addicts and found that the abstinence symptoms from morphine could be controlled with methadon. When methadon was withdrawn abruptly after prolonged administration, the abstinence syndromes were so mild that treatment was not necessary.

Kirchof and David[7] have studied this drug in 84 patients in doses ranging between 5 and 15 mg. and reported that the control of pain was adequate and side effects were minimal. They did not observe withdrawal symptoms, sedation or hypnosis.

Scott, Livingstone, Jacoby and Broberg[8] have given methadon preoperatively and have observed the drug to be inferior to morphine due to its lack of sedative properties. However, it was found to be an effective analgesic.

Scott, Kohlstaedt and Chen[9] have reported use of this analgesic in a series of 210 patients, with 72.9 per cent obtaining complete relief of pain. The incidence of side effects in their patients was minimal and relatively unimportant.

Gentling and Lundy[10] have used methadon in 106 patients with a variety of diseases and reported that all but 4 patients had satisfactory relief of pain.

In April 1946 clinical trials of the drug were instituted at the University of Minnesota Hospitals. Up to the present time methadon has been given to a total of 400 patients for relief of all types of pain. This group consists chiefly of adults, except for 10 children.

Approximately 85 per cent of the drug was obtained from the Eli Lilly Laboratories, Indianapolis, under the name of "dolophine." The rest of the drug was supplied by the Winthrop Chemical Co., Inc., as "adanon," by the Abbott Laboratories as "AN 148" and by Parke, Davis & Company as "diaminon."

Some of the conditions for which it was used to alleviate pain were: postsurgical, primary and metastatic carcinoma, arthritis, herniated disk, thalamic pain, myalgia, neuritis, headache, ulcer of the leg, anginal pain, cholecystitis, common duct stone, dysmenorrhea, labor and gastric and duodenal ulcers.

The methods of administration were oral (as capsules, tablets and elixir), hypodermic and intravenous. Onset of action was two minutes when given intravenously, within fifteen or twenty minutes when given hypodermically, or when given orally as the elixir, and thirty minutes when given orally in capsules or tablets. By all routes of administration it was found that the average duration of action was from three to four hours, with many of the patients obtaining relief for as long as eight to twelve hours. The majority of patients received the drug hypodermically at three to four hour intervals as necessary. When continuous use of analgesics was indicated, the elixir was substituted successfully for hypodermic injection on the patient's discharge from the hospital. No appreciable difference in potency was found between hypodermic injection and the oral administration of the elixir. However, in equivalent amounts the capsules and tablets were found to be inferior to the hypodermic, intravenous and elixir forms of the drug, requiring almost twice the dose to produce the same effects.

Originally, 2.5 and 5 mg. doses of methadon were used. The 2.5 mg. doses relieved only the mildest pain, while 5 mg. doses relieved only moderately severe pain. The doses were therefore increased to 7.5 and 10 mg., which were adequate to relieve patients experiencing extremely severe pain. In 1 patient in the terminal phase of generalized leukemic reticuloendotheliosis, 15 and 20 mg. of the drug administered intravenously every two hours were necessary for the relief of excruciating bone pain. Methadon in doses of 10 mg., either hypodermically or intravenously, proved to be more effective than 15 mg. of morphine in this patient.

A summary of the number of patients, type of pain treated and degree of relief obtained is shown in table 1. All degrees of pain, all doses from 2.5 to 20 mg. and all routes of administration are included, although not indicated, in the tabulation.

Table 3.—*Incidence of Side Effects*

Headache	19	6	33	4		2	2				2	
Miscellaneous	89	8	11	3		3	3					2

Sixty-seven side effects occurred in 52 patients; 13 per cent of patients had side effects.

Eighty-one per cent of the patients had adequate or complete relief of pain, and this figure would be increased to 86 per cent if the group of patients who received methadon for labor pains were excluded, since the drug has proved to be ineffective in this type of pain. Effects of methadon that were particularly notable were the minimal amount of sedation, the low incidence of psychologic phenomena, such as euphoria and clouding of mentality, and the presence of a relaxing effect. Most patients expressed pleasure in being able to carry on with normal activities even when receiving 10 mg. of the drug hypodermically every three hours.

It was possible to use methadon to relieve muscular spasm and pain in patients with bulbar and spinal poliomyelitis even when they were confined in respirators because of the minimal sedative effect. Doses of 5 mg., and occasionally 7.5 mg., were adequate and did not produce any respiratory difficulty. The effects of this drug were striking in these cases, since other narcotic analgesics or barbiturates caused severe respiratory depression.

Methadon was also used effectively to relieve headaches due to brain tumor, head injury, brain abscess and hemiplegia and headaches following encephalograms and ventriculograms without encountering any undesirable depressant effects.

Obstetric patients in labor received doses of 5 to 10 mg. without resulting cyanosis of the infant, but the analgesic effect was inferior to that of meperidine hydrochloride.

When incorporated in a syrup, the drug is effective in depressing the cough reflex and has been used by several patients in whom other medicaments had failed; however, the incidence of side effects is relatively high.

Morphine and meperidine hydrochloride were used alternately with methadon in 90 patients during the course of therapy for comparison of effects. In doses of 5 to 10 mg. methadon proved to be more effective than meperidine hydrochloride in any dosage from 75 to 150 mg. When effects of 5 mg. doses of methadon were compared with 10 to 15 mg. doses of morphine, there was a slight preference for morphine. However, 7.5 and 10 mg. doses of methadon were somewhat more effective than 10 and 15 mg. doses of morphine. It was found that the analgesic effect of 10 mg. of methadon was equal to that of 15 mg. of morphine or 150 mg. of meperidine hydrochloride and in many cases was superior. This observation was also made independently by Kohlstaedt[11] and his associates, both clinically and experimentally. A summary of the comparison of methadon with morphine and meperidine is shown in table 2.

Side effects were present in 13 per cent of the patients and included nausea and vomiting, sedation, euphoria, pinpoint pupils, amnesia, dry mouth, headache and itching, as noted in table 3. When divided into groups according to dosage it was found that the incidence of side effects was 13 per cent in the 232 patients that received 5 mg. of methadon, 12 per cent in the 104 that received 7.5 mg. and 22 per cent in the 57 patients that received 10 mg. It therefore appears that 5 and 7.5 mg. doses would be most satisfactory for general use from the standpoint of freedom from toxic reactions.

Nausea and vomiting occurred chiefly in ambulatory patients who took the drug in elixir form for dysmenorrhea and headaches. Hyperdermic administration of the drug for the same conditions produced this effect infrequently. The sedation produced was generally a slight drowsiness. However, in 2 patients over 60 years of age who had complicated postoperative courses, a dose of 7.5 mg. administered every four hours caused sufficient respiratory difficulty to warrant discontinuation of the drug. The relatively low incidence of euphoria may prove to be a handicap in severely depressed patients, although it was necessary to change to morphine for this reason in only 1 patient, who proved to be a difficult nursing problem because of his depression. Pupillary changes were noted only in 3 patients in whom miosis occurred. Dizziness occurred principally in ambulatory patients. Itching was severe in two patients, but was relieved by diphenhydraminehydrochloride ("benadryl hydrochloride" N.N.R.). It was not necessary to discontinue methadon in either of these patients, and both are continuing to take the drug with no recurrence of itching even though administration of diphenhydramine has been discontinued.

---

[11] Kohlstaedt, K. G.: Personal communication to the author.

Prolonged administration of methadon at regular intervals up to twelve months did not cause associated constipation or change in bowel habits. There has also been no effect on the hemoglobin or white blood cell counts.

Development of tolerance occurred in some patients who were at first adequately relieved by a dosage of 7.5 mg. but later required 10 mg. It was also necessary to decrease the three to four hour interval between administrations to one to two hours. Most of these patients had generalized carcinomatosis, and an increasing severity of pain during the last few days of life may have been a factor.

Thus far there has been no evidence of addiction in the sense that physical dependence and withdrawal symptoms occur. Approximately 20 patients receiving methadon for two or three months had no withdrawal symptoms on abrupt discontinuation of treatment. Three patients who have been treated with the drug for one year have all been able to decrease dosage at will and to discontinue use for as long as two to six weeks without ill effects. It is believed, however, that this relatively small number of patients does not warrant a final statement concerning addiction.

It was possible to replace morphine, meperidine, "pantopon" (the total alkaloids of opium as soluble hydrochlorides) and dihydromorphinone with methadon in persons addicted to each of these drugs. The dose used and the frequency of administration depended on the amount of drug the addict was accustomed to taking. None experienced withdrawal symptoms during the time the narcotic was being withdrawn or after the termination of treatment with methadon.

Thus far contraindications to the use of this drug have not been encountered, and it has been used successfully in patients with idiosyncrasies to morphine and to meperidine. In patients with dysmenorrhea and headache the routine use of the elixir is not encouraged because of the high incidence of nausea and vomiting. In obstetric analgesia the results produced are not as satisfactory as those of meperidine.

SUMMARY

Methadon, a new synthetic analgesic, has been used clinically in various types of pain and has been compared with morphine and meperidine.

1. The drug has characteristics of both morphine and meperidine.
2. Oral use of the elixir is almost as effective as the hypodermic injection.
3. Ten mg. of methadon is as effective in relieving pain as 15 mg. of morphine or 150 mg. of meperidine.
4. Adequate or complete relief of pain occurred in 81 per cent of 400 patients.
5. Less sedation and euphoria occur with methadon than with morphine.
6. Side effects occurred in 13 per cent of patients.
7. Tolerance to the drug may develop.
8. Addiction has not been definitely established.

ENCEPHALITIS AS A CAUSATIVE FACTOR IN BEHAVIOR DISORDERS OF CHILDREN

An Analysis of Seventy-eight Cases

J. VICTOR GREENEBAUM, M.D. and
LOUIS A. LURIE, M.D.
Cincinnati

The following report is of observations made on 78 children who were referred to the Child Guidance Home because of personality difficulties and behavior disorders which were found to be causally related to a previous attack of encephalitis. At this point a word about the procedure which has been employed at the Child Guidance Home since its inception in 1920 is appropriate. Every child admitted for observation is studied from the psychobiologic point of view, which entails a knowledge and understanding of all the factors, physical, psychiatric, psychologic and sociologic, which may be involved in a given case; in other words, a study of the total situation, a procedure which has been recently emphasized by various authors.[1] It was only after the evaluation of the findings made from such an extensive study that the aforementioned relationship in the 78 cases was made. Furthermore, the excellent facilities of the institution for follow-up permitted a continuous dynamic study, which in some cases covered more than twenty-five years. This is the third report based on this continuing study, the first two being concerned with only 50 cases. Excerpts from these two papers are embodied in this report for the sake of completeness.

Among the conclusions reached as the result of the first two studies were the following:

> Encephalitis following acute virus or bacterial infections or cerebral trauma early in childhood may lead, in addition to structural cerebral changes, to behavioral and personality disturbances of such gravity as to prevent normal adjustment to life; this, despite the fact that the intellect may be unimpaired . . . . Encephalitis illustrates better than any other disease that changes in the structure of the brain may lead to changes in function. Since the encephalitic process may attack any part of the brain, the disorganization of function will correspond to the level or levels of the brain stem involved. Hence, vegetative, motor or intellectual dysfunction either alone or in combination may be present.[2]

Read before the Section on Pediatrics at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J. June 11, 1947.

J. **41**: 1018 (Nov.) 1945. Lurie, L. A.; Greenebaum, J. V.; Leichtentritt, B., and Rosenthal, Florence M.: Late Results Noted in Children Presenting Postencephalitic Behavior, Am. J. Psychiatry, **104**: 171 (Sept.) 1947.

These conclusions have been strengthened by the study during the past five years of the additional 28 cases reported in this series.

Of the 78 children constituting this series, 61 were boys and 17 were girls, and their ages at the time they were referred for study ranged from 4 to 19 years (fig. 1). The general proportion of boys to girls studied at the Child Guidance Home has been in the ratio of 2 to 1. In this series the ratio is almost 4½ to 1. This would appear to agree with the findings of other investigators; namely, that boys appear to be more apt to show postencephalitic type of behavior and personality changes than girls. The 78 children were taken from an unselected series of 2,700 children presenting all types of behavior disorders. This gives an incidence of 2.85 per cent.

According to figure 2, approximately 50 per cent of the patients were admitted for study during the years 1940 to 1946. The exact age of onset of the disease was unknown in 12 cases. Eighty per cent of the known cases fall in the age range of 5 months to 7 years. The remainder are scattered over the remaining 11 years (fig. 3). Both these findings correspond to those of a study of acute encephalitis made at the Children's Hospital and the Cincinnati General Hospital.[3] In a series of 113 cases of acute encephalitis observed between the years 1919 and 1947, 91, or over 80 per cent, also occurred in children under the age of 7 and 98, or 87 per cent, similarly occurred between the years 1940 and 1946.

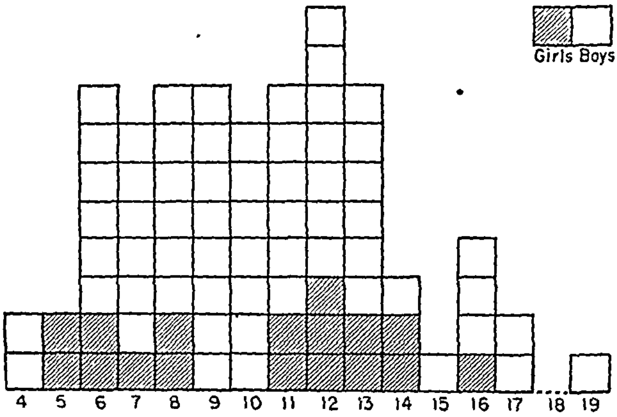

Fig. 1.—Distribution according to age and sex.

Table 1 shows the types of encephalitis as ascertained from the medical histories. From this it will be seen that the majority (37) were of the virus type, 29 of the toxic type and 12 of the traumatic type.

The age range of onset of the behavior difficulty or personality change showed a rather wide scatter with two peaks, one 3 to 4 years and the other 10 to 11 years. The age of onset of the problem was not learned in 6 cases (fig. 4).

In 64 cases the interval in years between the onset of the illness and the time of the onset of the problem was as follows: no interval or immediate onset in 40 cases; one year interval in 14 cases; two year interval in 3 cases; three year interval in 2 cases; five year interval in 2 cases; eight year interval in 2 cases, and nine year interval in 1 case. In 14 cases, the exact time of onset of the problem could not be determined.

It is interesting to note that although behavior disorders and personality changes were noted immediately after the onset of the disease in most of the cases, not one of the 78 patients was referred for study during the acute phase of the illness. All were referred at much later dates when persistent behavioral or personality difficulties made them severe problems to their parents or to their communities.

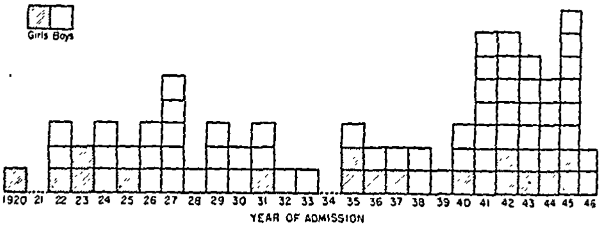

Fig. 2.—Distribution of cases of encephalitis according to years of admission to the Child Guidance Home, 1920 to 1946.

The majority of the children were referred for more than one type of behavior disorder. These ranged from such simple behavior complaints as incorrigibility, truancy and temper tantrums to the more severe types of antisocial behavior in the form of sexual misconduct, stealing and other delinquent and criminal acts. In addition some presented serious abnormal types of behavior such as extreme restlessness, delusions and hallucinations.

NEUROLOGIC AND ELECTROENCEPHALOGRAPHIC ABNORMALITIES

Neurologic abnormalities were noted in all but 21 cases. In 38 cases there were pyramidal signs; in 20 cases, extrapyramidal signs, and in 16 cases, ocular symptoms. Three children had persistent petit mal attacks and 6 suffered from grand mal seizures. Seven children showed the typical signs of parkinsonism.

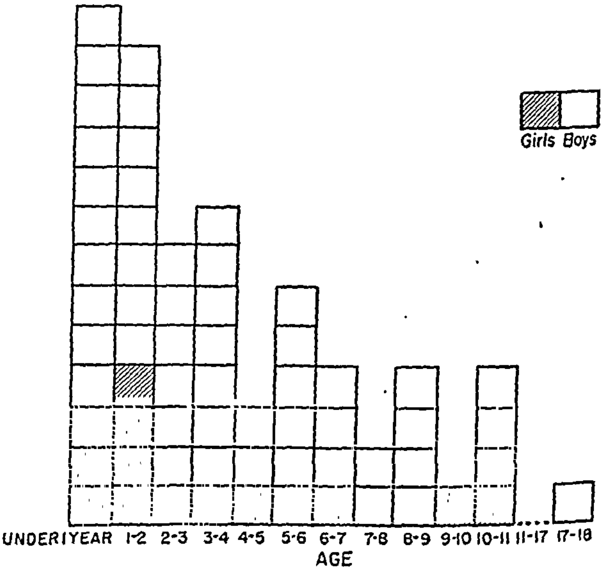

Fig. 3.—Age range of onset of disease.

---

[3] Stine, F. A.: Personal communication to the authors.

[4] These interpretations were made by Drs. G. Maltby, G. Engel and H. Lederer of the Cincinnati General Hospital.

Electroencephalograms were made in 15 cases. In 6 cases, the tracings were normal; in 8 abnormal, and in 1 case questionable. The abnormal tracings were of two types: (1) typical tracing of epilepsy and (2) tracings which showed generalized cerebral dysrhythmia characteristic of psychomotor disturbances.[4] In 3 of 4 cases with no neurologic abnormalities noted, the electroencephalographic tracings were normal. In 6 cases with observed neurologic abnormalities, the tracings were normal in 5 cases and questionable in 1 case. In the remaining 5 cases, both the neurologic findings and the electroencephalographic tracings were abnormal.

According to the results of the psychometric tests made at the time of their admission to the Child Guidance Home, 3 children in this series rated superior, 26 were of average intelligence, 17 were subaverage, 14 rated borderline and only 18 were feebleminded (table 2). Psychometric examinations were repeated in 47 cases several years after the children's dismissal from the Child Guidance Home. The intelligence quotients remained the same in 9 cases, improved in 1 case and deteriorated in 37 cases.

Psychotic	16
Total	78

At the Child Guidance Home every child is typed on a special personality chart. Sixty-one of the children (approximately 80 per cent) in this series received a uniform personality rating which was fairly distinctive and characteristic. In general these children were suspicious, impulsive, egocentric and selfish. They exhibited violent temper tantrums and were extremely obstinate. Emotional instability, unreliability and lack of initiative were outstanding shortcomings. They lacked ability to concentrate and showed little or no self control, their behavior being extremely unpredictable.

The remaining 17 children in the series received a nondescript personality rating in which the various characteristics enumerated were not uniformly present.

Rorschach tests were made in 10 of the last of 28 cases studied. The results were for the most part in agreement with the general characterization of the postencephalitic type of personality structure as shown in the cases cited. This will be the subject of a later paper.

TYPES OF ABNORMAL BEHAVIOR

The abnormal patterns of behavior which these children exhibited can be readily divided into three groups: (1) simple behavioral disturbances; (2) psychopathic behavior, and (3) psychotic behavior. Of the 78 cases, 26 presented simple behavioral difficulties, 36 showed psychopathic type of behavior and 16 showed psychotic type of behavior (table 3).

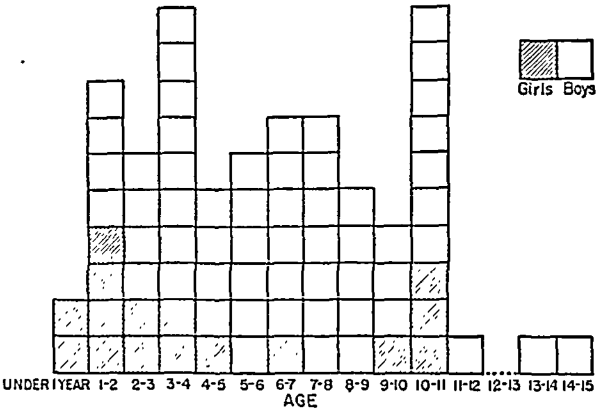

Fig. 4.—Age range of onset of problem.

Group 1.—The children who came under the simple behavioral classification were restless and hyperactive and exhibited temper tantrums. They were noisy and domineering. Aggressiveness was an outstanding symptom. Stealing, lying and running away were frequent occurrences. Enuresis was often present. These children were extremely difficult to control.

Group 2.—Of those who presented psychopathic types of behavior, some were phlegmatic and apathetic and apparently indifferent to what was going on around them. They gave the impression of being dull intellectually, even though their intelligence quotients, as shown on the psychometric tests, were normal or above normal. They were asocial and made little effort to enter into group activities. They concentrated poorly and were either unable or unwilling to carry out instructions. The majority of this group, however, were extremely restless and hyperactive, and lacked ability to concentrate.

In many instances, they were vicious, cruel and apparently deliberately abusive to other children. The unpredictability of their behavior was outstanding. Night terrors, sleep walking, breathing difficulties, food fads and habit tics were frequent complicating symptoms.

Group 3.—Those children who were classified as psychotic showed severe disorganization of cerebral function. They were careless of their personal appearance and were slovenly in all their habits. Moodiness, crying spells and irrelevant talk were often noted. Outbursts of screaming and causeless laughter were also often present. Occasionally hallucinatory phenomena were in evidence. These children had no insight whatsoever into their condition. It was impossible to control them, and they became violent when thwarted. Some refused to wash, bathe or change their clothes, often insisting on going to bed in the clothes which they had worn during the day. Rapport with them was impossible. Their behavior was comparable in many respects to that of the hypomanic. Some of these cases had been diagnosed as schizophrenia.

Case reports illustrating each of these 3 groups are appended.

As has been stated, the children in this study have been followed for periods ranging from three to twenty-six years, the majority having been followed for more than fifteen years. Their present age range is from 10 to 43 years.

COMPARISON OF ADJUSTED AND UNADJUSTED GROUPS

In the great majority of the cases, various types of social and medical therapy have been tried in order to bring about a social adjustment or at least an amelioration of the symptoms. The results have been highly disappointing. Only 12 of the 78 patients are at present adjusted. In the adjusted group there were 9 boys and 3 girls. Eight had had the virus type, 3 the toxic and 1 the traumatic type of encephalitis.

* For convenience in typesetting the letters which might be circled in pen and ink in an actual form are set in italics.

Comparison of the adjusted and unadjusted groups reveals some rather significant differences. In the unadjusted group (66) there is a preponderance of the toxic and traumatic forms of encephalitis. Severe neurologic sequelae were also more prevalent, convulsive seizures having developed in 8 of the children in this group in contrast to but 1 in the adjusted group.

A noticeable and significant difference between the two groups was the much greater number of children in the unadjusted group who showed intellectual deterioration; specifically, 34 (51 per cent) in the unadjusted group compared with only 2 (16 per cent) in the adjusted group.

Another significant difference was the proportionately larger number of children in the unadjusted group who have the typical personality structure characteristic of the postencephalitic. There were 54 (82 per cent) in the unadjusted group in contrast to 7 (58 per cent) in the adjusted group.

There was also some difference in the two groups with respect to types or patterns of behavior. The number of children exhibiting psychopathic and psychotic behavior was far greater in the unadjusted group, 70 per cent compared to 58 per cent in the adjusted group. This was especially noticeable in the number showing psychotic reactions.

These differences, therefore, furnish a possible prognostic basis for the determination of the ability of the child showing postencephalitic behavior to adjust socially.

COMMENT

Our series of 78 cases was taken from a group of 2,700 children showing all types of behavior disorders, which gives an incidence of approximately 2.9 per cent. This is a significant percentage. From our experience with postencephalitic type of behavior we feel that the disease, as a complication of acute infectious and contagious diseases of children, is frequently overlooked. One of the reasons for this may be the fact that the neurologic examination often fails to disclose any abnormality. Another reason, and probably a more potent one, is the fact that in the great majority of cases there is no history of an attack of encephalitis. It is only when the medical history of the child as well as his behavioral reactions are carefully scrutinized and evaluated from the standpoint of a possible encephalitic episode, complicating an acute infectious or contagious disease occurring in the first decade of life, that the condition becomes apparent. We are in agreement with Bender[5] that "the diagnostic criteria for encephalopathic behavior disorders are now considerable. Even without the history of a specific etiological factor or evidence of the specific (neuro)pathology, the diagnostic methods which may be applied to fields of behavior are sufficient to establish a diagnosis."

One must consider the possibility of postencephalitic type of behavior when confronted with a child who is extremely hyperactive, restless and destructive, has a short attention span, is highly distractible, lacks self control and whose actions are extremely unpredictable.

---

[5] Bender, quoted by Neal, J. B.: Encephalitis: A Clinical Study, New York, Grune & Stratton, Inc., 1942, pp. 379-380.

Furthermore, the longer a case is followed, the more characteristic the clinical picture becomes. Often where the condition was originally only suspected, reexamination later easily established the correctness of the tentative diagnosis. As time goes on the pattern of behavior and characteristic personality changes become more clearcut and pathognomonic. The first 2 cases cited in this report illustrate this point clearly. If these facts are borne in mind, many more cases of uncorrectable behavior disorders and irreversible personality changes will be found to fall into this category.

SUMMARY AND CONCLUSIONS

A report on the study of 78 children presenting behavior disorders and personality changes following an attack of encephalitis is presented.

The cases were followed for periods ranging from four to twenty-six years, the majority having been followed for more than fifteen years.

Of the 78 children constituting this series, 61 were boys and 17 were girls, a ratio of more than 4½ to 1. This tends to bear out the findings of other investigators that boys are more apt to show postencephalitic type of behavior and personality changes than girls.

The 78 children comprising this series were taken from an unselected series of 2,700 children studied as inpatients at the Child Guidance Home, who presented all types of behavior disorders. This represents an incidence of approximately 2.9 per cent and indicates that the condition is by no means rare. The diagnosis will be made with even greater frequency once it is recognized that it can be made on the basis of the characteristic behavior reactions and personality changes even without a specific history of a previous attack of encephalitis or the presence of neuropathologic changes.

The age range of onset was in the first decade of life in 60 of the cases, 43 occurring before the age of 5 years. Furthermore, the younger the patient when affected by the disease, the greater the likelihood of psychiatric sequelae.

The types of encephalitis as ascertained from the medical histories showed that the majority (37) were of the virus type, 29 of the toxic type and 12 of the traumatic type.

In the great majority of the cases the behavior difficulty or personality change was noted immediately after the attack of encephalitis.

The majority of the children were referred for multiple behavior problems. These covered the usual range of problems ordinarily studied at child guidance clinics.

The abnormal patterns of behavior which these children exhibited could be readily divided into three groups: (1) simple behavioral disturbances, (2) psychopathic behavior and (3) psychotic behavior.

When these children were first studied, 14 were found to be feebleminded and 7 rated borderline. The remainder (57) were either of average or of superior intelligence.

Forty-seven of the children were retested several years later. The intelligence quotients remained the same in 9 cases, improved in 1 case and deteriorated in 37 cases. The frequency of intellectual deterioration is worthy of note as it seems to refute the prevailing belief that the most severe and lasting damage is in the emotional sphere in contrast to the preservation of the intellect.

Neurologic abnormalities were noted in all but 22 cases. These were of both the pyramidal and the extrapyramidal type. Ocular symptoms were present in 16 cases. Three children had petit mal attacks and six suffered from grand mal seizures. Seven children showed symptoms of parkinsonism.

Electroencephalograms were made in 15 cases, of which 8 were abnormal. The abnormal tracings were of two types: (1) tracings typical of epilepsy and (2) tracings showing generalized cerebral dysrhythmia, characteristic of psychomotor disturbances.

Sixty-one (80 per cent) of the children in this series had a uniform and characteristic personality makeup. In general, lack of inhibition, restlessness, impulsiveness, extreme distractibility and unpredictibility of behavior were the dominant personality traits.

The prognosis from the standpoint of social adjustment is poor. Only 12 children in this series of 78 have made a fair social adjustment; this despite the application in the majority of cases of the best available medical, psychiatric and social therapeutic technics.

The failure of social therapy and psychotherapy in these cases cannot be attributed to faulty social or psychiatric technics. Rather, such failure indicates that the problem of the child presenting postencephalitic behavior disorders or personality changes is not solely one of psychopathology and psychodynamics. The psychopathologic symptoms are primarily the results of the neuropathologic changes, and it is our present inability to correct the latter which accounts for the failure of treatment. These cases illustrate pointedly the relation of structure to function in human behavior. For this reason, it is essential for all who are interested in behavior disorders of children, particularly pediatricians, to use the classic psychobiologic approach when studying problem children.

REPORTS OF CASES

CASE 1.—Billy, aged 10, was admitted to the Child Guidance Home for the first time in June 1941 because he was unable to adjust either at home or at school. He felt that every one picked on him, and in turn his classmates complained that he hit, pinched and bit them.

According to the social history, the father and mother were incompatible. The father drank heavily and consorted with other women. The mother appeared to be a rather stable person, who considered herself responsible for the support of her family because of her husband's incompetence. Her attitude toward the child was one of overprotectiveness, and toward her husband one of resigned indifference. She worked during the day and the father worked at night. Consequently, the boy had little supervision and little association with his parents. The father felt that Billy's problems were entirely due to the family situation. He stated that he, the father, was the only one to whom the boy had ever been really attached. The constant friction in the home made for a tense, unhappy situation. The boy received neither love nor affection from his parents and felt insecure. Of significance in the boy's medical history was the fact that he had had a severe attack of measles early in infancy which was complicated by bilateral otitis media.

At the Child Guidance Home the physical and neurologic examinations disclosed no significant abnormality. The boy had an intelligence quotient of 121. He was hyperactive and restless, and concentrated poorly. He was unable to get along with the other children and did not hesitate to throw rocks at them without any apparent cause. He was a poor sport and a coward. The children heartily disliked him and kept out of his way as much as possible. In psychiatric interviews the boy talked quite freely. He told about his home situation and said that he had been moved around a great deal. He admitted that he could not get along with children at school and said that sometimes they called him "sissy." This was because he would cry and run away if he found that he was getting the worst of any situation. He thought it might help if he were bigger and stronger and better able to stand up for himself. He stated that he did not want to live with either one of his parents alone. What he really wanted was to have a normal home with both parents present. He was well aware of the friction between his parents and was unhappy about this. The boy appeared to have fair insight into his condition. His lack of security and feeling of inferiority were evident.

The diagnosis at this time was that most of Billy's difficulties were due to faulty parent-child relationships. It was recommended that the boy be placed in a good boarding home where he would receive the love and affection of which he had been deprived, and where he could develop a feeling of security. The recommendation was carried out. However, despite intensive social therapy, the boy did not adjust in this and in other homes in which he was subsequently placed. He was then placed in a Children's Home, where he also failed to adjust. The Children's Home asked that the boy be readmitted to the Child Guidance Home for further study. The physical and neurologic findings at this time were approximately the same as they had been at the time of his previous study. His intelligence quotient was still 121 and his social quotient 103. Billy's behavior reactions followed the same pattern as they had on previous study except that they were more extreme. He was provocative, restless and aggressive, had a short attention span, was undependable, destructive and slovenly about his person. The boy stole and tried to lie out of every situation. A Rorschach test made for the first time revealed strong evidence of cerebral damage. His rating on the personality chart was characteristic of the postencephalitic. The electroencephalographic tracing, however, was normal. On the basis of the present observations and the medical history of a severe attack of measles early in infancy complicated by a bilateral otitis media, it was felt that the boy was presenting a postencephalitic type of behavior. The unwholesome home situation and the faulty parent-child relationships were also contributory but only in the sense that they had determined the trend or direction of the antisocial behavior. A recommendation for special institutional placement was made, but this could not be carried out as there was none available. Billy was therefore returned to Children's Home and placed in a cottage with older boys. There he again presented so many difficulties that the Children's Home refused to keep him. The only other available placement was a school for delinquent boys, where he was placed. There he proved to be most difficult. He ran away repeatedly, and after a short time had to be taken home by his mother. Then the neighbors began to complain and reported that he had stolen, pulled the main light switches in apartment buildings, and rung apartment doorbells late at night. They became so upset by his behavior that they went to court, demanding that drastic measures be taken. His teachers also stated that he was the worst problem they had ever encountered. In court, the mother promised to send the boy to a military school. After a brief stay there, the military school refused to keep him. The child was again brought before the court, and at the court's request he was readmitted once more to the Child Guidance Home for further study. At this time the neurologic examination showed some positive findings in the form of right internal strabismus with bilateral nystagmus, general muscle weakness with beginning atrophy of the muscles of the right forearm, and absent abdominal reflexes. The boy's intelligence quotient had dropped to 108. His behavior at the Home was extremely belligerent and he was abusive to the other children. He ran away several times and proved to be a nonconformist in every way. Psychiatric interviews were not very productive, as it was difficult to make satisfactory rapport with him. He bragged about his escapades and stated constantly that he had done nothing wrong and that every one else was to blame for his difficulties. Although he had been in many serious difficulties he minimized these and refused to admit that he had committed any wrong.

All who observed the boy felt that he was potentially dangerous and that in order to protect society it was necessary to institutionalize him. The only available placement was a hospital for the mentally ill, where he was admitted late in 1945 at the age of 14.

Comment.—This case illustrates the insidious nature of the disease in a boy whose behavioral difficulties at first appeared to be due entirely to faulty personal and interpersonal family relationships. However, on repeated examinations made over a period of years, it became apparent that his continued antisocial behavior was on an organic basis. This was first suggested by the interpretation of the Rorschach test. Furthermore, despite the fact that there was no history of an attack of encephalitis, the history of a severe attack of measles complicated by bilateral otitis media plus neuropathologic findings and the distinctive pattern of the boy's behavioral reactions warranted the diagnosis of postencephalitic behavior disorder. Admittedly, he is not properly placed in a hospital for the insane, as he never manifested any psychotic symptoms but merely uncontrollable antisocial behavior.

CASE 2.—William, a white boy aged 13, was admitted to the Child Guidance Home in January 1930. The reason for his referral was that he had been involved in petty thefts and truancy for a long time. The social history revealed that his delivery had been instrumental, the mother dying in childbirth. The father was an alcoholic addict, and was killed by a train when William was 2 years of age. At first he was cared for by maternal aunts, and later he was boarded out. There was little material available regarding his early developmental history. It was noted, however, that the boy had suffered from various acute infectious diseases in infancy and early childhood with chronic involvement of the middle ear.

The physical examination made at the Child Guidance Home revealed no significant abnormality except for bilateral otitis media, with a loss of hearing of approximately 50 per cent in both ears. In the neurologic examination there were many positive findings in the form of unequal pupils and pyramidal tract signs. His intelligence quotient was 109.

At the Home, William proved to be a friendly boy who was liked by every one because of his frankness and willingness to be of service. It was noted that he was emotionally unstable, was socially immature and showed a strong feeling of insecurity. He was unable to carry out his good resolutions, although he apparently tried hard. He composed well, was a good musician and a leader in the club activities. He loved the Child Guidance Home and begged to be allowed to remain permanently. The boy talked freely and willingly in psychiatric interviews. He made good rapport with the psychiatrist and social workers. He appeared to have some insight into his condition. He admitted that he was weak willed, had many fears and always needed some one on whom he could lean. New experiences particularly frightened him. At this time it was felt that despite the fact that the boy was suffering from an organic involvement of the central nervous system of unknown origin, the unfortunate early conditioning had made the boy antisocial. It was therefore recommended that he be placed in a school where he would be under strict disciplinary care and at the same time would receive psychotherapy. This recommendation was not carried out, and he remained with the aunt with whom he had been living. However, his truancy from school became such a problem that, at the insistence of the Attendance Department, the aunt placed him in a private military school where he remained for some time. Returning to his aunt for his summer vacation, he immediately got into trouble. He was charged with stealing, attacking a 5 year old girl, and driving a stolen car to a far distant city. He was then cited to court. Before he could be tried, the aunt returned him to the military school, but he ran away almost immediately, returning to Cincinnati, where he lived at several different hotels, giving fictitious names and leaving the hotels without paying. Again the boy was brought into court and referred to the Child Guidance Home for another period of observation.

Here it was noted that with the exception of the chronic otitis media, which had become worse, the results of all the physical examinations were essentially the same as on the first examination. The boy was still friendly and gregarious. However, he concentrated poorly, was unreliable and irresponsible. In psychiatric interviews, the boy's extreme immaturity was apparent; likewise, his poor concentration and ability to follow through. He admitted being weak willed and said that he readily followed any leader and so became involved in trouble. He stated that he was more restless than he had ever been and just wanted to run away from everything. Everybody and everything irritated him and he felt at times that he could not control himself. In one interview he said, "I'm afraid of the beginning of everything and afraid I can't do it. I like people after I'm with them and I get along with them. I'm unhappy. I don't like being on my own and I always get into trouble where I am." At this time the diagnosis was that the boy's behavior problems were due in part to an organic brain involvement probably as a result of some acute infectious disease, which had been complicated with encephalitis. The recommendation for custodial care in a special kind of institution, equipped to care for cases of that type for life, was recommended.

Again the recommendation was not carried out. Shortly thereafter, word was received that the boy had been arrested in Los Angeles, where he was committed to the Preston State School. Later in the year, William returned to Cincinnati. Following this, his aunt again placed him in a military school from which he promptly ran away.

William's history from that time on was a repetition of what had gone on before. He refused to stay in any one place, held jobs for just a few days, incurred debts, stole and burglarized. During the succeeding years, he was in the city workhouse, the boys' industrial school (state reformatory) and federal reformatory, where he is at present.

Comment.—When first seen at the age of 13, the diagnosis of postencephalitic behavior disturbance was not made in spite of neurologic findings and the presence of a chronic discharging ear. However, subsequent observation of the boy's behavior proved that the organic brain changes, encephalitic in nature, were basically responsible for his intractable and irreversible psychopathic behavior. Obviously incarceration in a reformatory is not the proper placement for a sick boy.

Case 3.—Roy was admitted to the Child Guidance Home in February 1927, at the age of 13 years. It was stated that the boy had been a behavior problem for two and one-half years. The social history revealed that the father had been in poor health for many years and that the mother was nervous because of worry over her son's conduct. She helped support the family by conducting a small notion store. They had been independent until just recently, when they were forced to ask for financial assistance from a local social agency. There were 4 siblings, 3 boys and 1 girl, all in good health and all doing well at school. They presented no behavior problems. The developmental history showed that Roy's birth and early development had been normal. He had had chickenpox, measles and whooping cough. The ages at which he contracted these were not stated. The boy had an attack of acute epidemic encephalitis at 9 years of age.

At the Child Guidance Home the physical examination disclosed no significant abnormality, but there were positive neurologic findings in the form of pyramidal tract changes. The boy had an intelligence quotient of 122. From the moment he entered the Child Guidance Home it was noted that he was extremely difficult to control. He was impulsive, egocentric, depressed and suspicious. He exhibited violent temper tantrums during which he was unmanageable. His emotional instability was pronounced. The children obviously annoyed him and he did not hesitate to bite pieces out of their arms and legs when he became angry. There was no one with whom he could get along. He was extremely irritable and a serious sex problem. He ran away five and six times a day. There was no way of appealing to him or obtaining his cooperation. He did as he pleased and did not hesitate to destroy or injure anything or any one in his path. He had unusual physical strength and on one occasion tore a tie off of one of the children. In forcibly removing the tie he almost choked the boy. On the other hand, there were times when Roy appeared to be tractable and affectionate. At such times he would put his arms around any one at the Home and act in a tender and loving manner, but a moment later his mood would change and he would try to injure the object of his former affection. Such bizarre behavior as plucking hair from a child's head or sticking another with pins was of frequent occurrence. He could not be left alone with the other children, and because of his unusual physical strength no adult person at the Home was able to handle him alone. The children were in mortal terror of him. In psychiatric interviews, contacts were on an extremely superficial level because of the boy's apprehensiveness, antagonism and unwillingness or inability to respond. Attempts to reassure him and to get him into a more responsive frame of mind were unsuccessful. In most of the interviews he refused to answer at all and would sit with his head in his lap. Occasionally he spoke about his family. He was bothered about the poor economic conditions in his home. He felt that his mother did not have enough money to take care of the family properly. He showed many fears, particularly of the laboratory tests. There was no evidence of delusions or hallucinations.

It was felt that the boy had had an attack of lethargic encephalitis with resultant psychiatric disturbances, principally in the sphere of volition. It was recommended that he be institutionalized. The parents were both ununderstanding and uncooperative, and made no attempt to carry out the recommendation. A year later the mother reported that the boy had been committed to the boys' industrial school (a state correctional institution) as a result of conviction on a charge of assault and battery. The boy's record at the industrial school was bad. He did not adjust in any way. He was paroled in March 1929 and returned to his home. A short time later he was arrested and sent to a state hospital for the mentally ill, where the same diagnosis as that given at the Child Guidance Home was made. Later in the year, another report from the hospital stated that he had become much more difficult, was quarreling with the other patients, attacking them and threatening every one with assault. In October 1931, the state hospital reported that Roy was home on trial visit. He was attending classes in high school. However, after being home for eight months, he had to be returned to the hospital because the family could not control him. Each year Roy's behavior has become more difficult. In January 1946, at the age of 32, he was still in the state hospital, where it was reported that his behavior was both bizarre and unpredictable. His intelligence quotient was still 122.

Comment.—This case illustrates the psychotic sequelae of lethargic encephalitis. In this instance there has been no intellectual deterioration even though the condition has existed approximately twenty years.

ABSTRACT OF DISCUSSION

Dr. Charles Bradley, East Providence, R. I.: The essayists' study originates from a Child Guidance Center fully staffed for studies of this nature. Their observations form a record of behavior patterns following encephalitis in children whom they had not known before the infection. Nevertheless, they are able to discern clearly certain personality characteristics varying in intensity without history of such previous behavior. My observations in connection with the Child Guidance Clinic and with a large contagious diseases hospital are similar to those of the essayists, and I am much disturbed because of inadequate facilities available for the care of hopelessly damaged children, as well as by the dearth of well trained child psychiatrists. The pediatrician is not equipped by training or mode of practice to undertake similar studies. However, to him should fall the task of early diagnosis. He is familiar with the personality patterns of his little patients and can be alert to changes following infection. He needs to be familiar with the total environment in which each of his patients lives and to have an understanding of adverse environmental pressures to which each may be subjected. Such knowledge would help immeasurably in differentiating between emotional and infectional trauma. But, more important, he needs to give attention to the possibilities of preventive measures. A total number of virus and bacterial infections seen by the pediatrician is great, and though only a small percentage contract postinfectious encephalitis, the number is not inconsiderable. I am firmly convinced that the institution of certain simple measures in management of the child with severe infection can be helpful as prophylaxis. I consider very important (1) bed rest at onset of infection, particularly for the hypertonic child; (2) at least three days of quiet bed rest after the afebrile period in severe infections has been reached, and (3) careful attention to the mental hygiene aspects of the care of the sick child, particularly the avoidance of traumatic experiences as exemplified by the administration of questionable therapy involving violent restraint of the patient.

Dr. Louis A. Lurie, Cincinnati: There is considerable diversity of opinion regarding the genesis of the psychopathologic train of events seen in postencephalitic types of behavior. According to some, the encephalitis merely brings out character defects and abnormal personality traits that were already present but had been dormant. According to others—and we agree with them—encephalitis does not necessarily accentuate the premorbid personality. As expressed by one investigator, "The tragic feature of encephalitis is personality change, not personality exaggeration." This belief seems to be borne out by the fact that the psychopathologic after-effects of encephalitis are much more pronounced in patients affected early in life. Furthermore, the study reported in this paper shows that the younger the patient affected by the disease, the greater the likelihood of the psychiatric sequelae. The same is true in whooping cough, and I think the reason for that is that the same pathologic changes occur in the brain in cases of encephalitis as they do in whooping cough; namely, petechial hemorrhages. Today the major trend in psychiatry is to explain human behavior in terms of freudian psychology. The tendency to minimize and even to ignore the role of somatic factors in the causation of abnormal behavior has proceeded to the point where even psychiatric social workers feel competent to diagnose and treat behavior disorders of children and adults without the aid of the physician or the psychiatrist. A thorough medical evaluation of the patient is not deemed essential. This attitude on the part of psychiatric social workers has been strengthened by the statements of some psychoanalysts that the usual setup of workers at child guidance clinics, consisting of a psychiatrist, psychologist and psychiatric social worker, can be dispensed with. The claim has been made that any person trained in psychoanalytic concepts and hence psychodynamically oriented is qualified to diagnose and to treat personality disturbances and behavior disorders. Such a trend must not be condoned. As physicians, we must recognize that we cannot separate function from structure. Genetically, function follows structure. The development of the psyche or mind has been coincident and coextensive with the increase in the structural complexity of the cerebral hemispheres; hence, anything that affects the structural integrity of the cortex must necessarily disturb the normal functioning of the psyche or the mind, and hence alter behavior. Encephalitis, as emphasized in this paper, illustrates this point exceptionally well.

PAPAVERINE IN CEREBRAL ANGIOSPASM (VASCULAR ENCEPHALOPATHY)

HENRY I. RUSSEK, M. D.
Director of Cardiovascular Research
and
BURTON L. ZOHMAN, M. D.
Consultant Cardiologist, Cardiovascular Division,
United States Marine Hospital
Staten Island, N. Y.

Papaverine relaxes many smooth muscles of the body, especially those of the blood vessels. Its therapeutic value has been demonstrated in arterial embolism, in which the drug increases collateral circulation by acting on reflexly constricted vascular channels. Similar therapeutic effect has recently been claimed from its use in angina pectoris and myocardial infarction. Indeed, the experimental and clinical observations of Katz[1] would indicate that papaverine enhances coronary blood flow in these disease states.

The action of papaverine on disturbances of the cerebral circulation has not thus far been reported. Embolism of the cerebral vessels would appear to be an indication for its use. The possible benefit from this drug in the therapy of angiospastic cerebral phenomena commonly observed in the course of hypertensive disease, acute glomerulonephritis, eclampsia gravidarum and lead poisoning has attracted the interest of the writers.

The cerebral manifestations encountered in these conditions vary widely. In the cases of milder disease transient aphasia or hemiplegia may be the only symptom. Headache and vomiting are common. Sensory disturbances consist of numbness, tingling or "crawling" sensations, localized or involving one side of the body, paresthesias of taste and smell as well as sudden temporary loss of vision in one or both eyes. Motor manifestations in the form of clonic convulsive seizures, either localized to one extremity or one side or generalized, are not infrequent. The more severe episodes are generally followed by an interval of clouded consciousness or coma from which the patient recovers in a few hours without recollection of the incident. The transient character of the seizures as well as the rapid clinical recovery following each of them strongly suggests that focal cerebral angiospasm initiates the episodes.

The purpose of this paper, therefore, is to record the results obtained with papaverine hydrochloride in the treatment of encephalopathy associated with hypertensive disease and cerebral vascular disease without hypertension. Although the series studied comprised 46 patients a review of several typical

case records will demonstrate the uniform results obtained.

REPORT OF CASES

CASE 1.—A white Italian woman aged 49 years complained of recurrent attacks of weakness of the left side of the body over a period of three years. Each attack would start with a "creeping" sensation in the left hand and forearm followed by spreading numbness and weakness of the entire left side of the body. Within recent months the patient suffered from five to twenty such attacks daily. The duration of the attack was from several minutes to one hour. Previous treatment with various sedatives failed to control the clinical symptoms. The patient was told that she had epilepsy and was given a trial on diphenylhydantoin sodium without benefit.

Physical examination revealed normal eye grounds. The blood pressure was 112 systolic and 70 diastolic. There was no enlargement of the heart, and no murmurs. There was a normal sinus rhythm with a ventricular rate of 78 per minute. Superficial and deep reflexes were normal. Examination during a typical attack revealed a left hemiparesis and a blood pressure of 120 systolic and 78 diastolic.

The patient was treated with 2 grains (0.12 Gm.) of papaverine hydrochloride and ¼ grain (15 mg.) of phenobarbital orally four times daily. Two mild attacks occurred on the first day of treatment. The patient became symptom free from the second day on. After four weeks of such treatment the dosage was reduced to 1½ grains (0.1 Gm.) of papaverine twice a day. For the ensuing week the patient experienced one or two mild seizures daily. The dosage was increased to the original level, and the patient has remained completely well during the past four months.

CASE 2.—A white Russian woman aged 76 years suffered from recurrent attacks of aphasia and clouded consciousness over a period of twelve years. In recent weeks she had had two to five attacks daily, each lasting from five to fifteen minutes. She had become bedridden during the previous five months because of fear of the seizures and weakness induced by protein deprivation prescribed by her physician. She drank ten to twelve cups of coffee per day.

Physical examination revealed an emaciated elderly white woman. The eye grounds revealed the changes of arteriosclerotic retinopathy. The blood pressure was 190 systolic and 82 diastolic. There was no enlargement of the heart. A soft systolic murmur was heard at the apex. There was a normal sinus rhythm with a rate of 80 per minute. There was no evidence of decompensation. Reflexes were normal.

Treatment consisted of 1½ grains of papaverine hydrochloride with ¼ grain phenobarbital orally three times daily. On this dosage the attacks continued but were diminished in frequency and severity. The patient was placed on a normal diet with coffee excluded. The dosage of papaverine was increased to 3 grains (0.2 Gm.) four times a day. There was complete cessation of attacks. The patient is ambulatory and has led a normal existence for the past year, during which time papaverine has been continued. An attempt to reduce the dosage of the drug on one occasion resulted in recurrence of attacks.

CASE 3.—A white Norwegian woman aged 72 years complained of frequent spells consisting of black circles in front of the eyes and tingling and numbness of the left arm and leg followed by weakness of the entire left side of the body. These symptoms recurred frequently over a period of four months. Each attack lasted several minutes to an hour. Within recent weeks she had had approximately ten attacks daily. Sedatives and hot towels to the head previously employed failed to control these episodes. Patient had had coronary thrombosis three years previously but had enjoyed fair health until the onset of the present symptoms.

Physical examination revealed arteriosclerotic retinopathy with grade 1 hypertensive changes. The blood pressure was 180 systolic and 88 diastolic. There was no enlargement of the heart; no murmurs were heard. There was a normal sinus rhythm and a rate of 84 per minute. There was thickening and tortuosity of the radial vessels. Reflexes were normal.

Treatment consisted of 2 grains of papaverine hydrochloride with ¼ grain phenobarbital three times a day. The recurrence of mild attacks necessitated an increase of papaverine to 4 grains (0.25 Gm.) four times daily, on which dosage the patient became symptom free. After a period of four months the dosage of papaverine was reduced to 4½ grains (0.28 Gm.) daily, and the patient has continued to remain asymptomatic for the past two months.

CASE 4.—A white Italian man aged 38 years with advanced malignant hypertension suffered from recurrent blindness and acute mania. His attacks recurred three to four times weekly, lasting one hour and followed by a period of coma from which he recovered without recollection of the incident. Enormous doses of sedatives failed to control or prevent these seizures.

Physical examination revealed grade 4 hypertensive retinopathy. The heart was moderately enlarged to the left. There was a systolic murmur at the apex. The aortic second sound was markedly accentuated. There was a normal sinus rhythm with a ventricular rate of 80 per minute. The blood pressure was 286 systolic and 160 diastolic. Reflexes were essentially normal.

The patient was given 3 grains of papaverine hydrochloride and ½ grain (30 mg.) phenobarbital orally four times daily. The patient worked for two weeks at his usual occupation without a single seizure. Attacks recurred after this period and necessitated hospitalization. Sympathectomy was performed without material reduction in the blood pressure. Cerebral episodes continued to recur during the postoperative period. The patient was then placed on 15 grains (1 Gm.) of papaverine daily and has suffered no attacks for a period of two months.

COMMENT

Our studies indicate that papaverine hydrochloride is of considerable value in the prevention of attacks of vascular encephalopathy. In most instances continuous administration of the drug resulted in complete cessation of symptoms. Papaverine abolished frequently recurring cerebral episodes in 2 patients who had suffered from this syndrome for a number of years. The drug was found effective in decreasing the severity and frequency of seizures even in some patients with advanced malignant hypertension.

Dosage varies considerably with each case. In some instances a daily dosage of 4½ grains was adequate to prevent the attacks. In others, symptoms continued to recur until 12 to 18 grains (0.75 to 1.2 Gm.) per day was administered. In a few cases the dosage has been considerably reduced without recurrence of symptoms. One case has required 9 grains (0.6 Gm.) daily for over a year to maintain freedom from attacks.

The toxicity of papaverine is low, so that the ingestion of ten times its therapeutic dose would not result in untoward effects.[2] It is devoid of narcotic action and causes neither sleep nor analgesia.

Although barbiturates failed to control the cerebral episodes in our cases, the combination of phenobarbital (grains ¼ to ½) with papaverine appeared to reduce the dosage of the latter required for clinical improvement. Conversely, the use of coffee or tea in excess seemed to vitiate the effectiveness of papaverine.

The cases studied do not substantiate the view that this cerebral syndrome is correlated with arterial hypertension.[3] Indeed, observation of several patients with cerebral vascular disease without hypertension disclosed normal blood pressure levels during typical seizures. Furthermore, in none of these cases was cardiac insufficiency a possible factor in the pathogenesis of the syndrome. It would appear, therefore, that vascular encephalopathy is a more appropriate designation than hypertensive encephalopathy for this cerebral symptom-complex.

[3] Fishberg, A. M.: Hypertension and Nephritis, Philadelphia, Lea & Febiger, 1939.

The favorable response in our cases to papaverine suggests the possibility of comparable benefit from this drug in the encephalopathic episodes of acute glomerulonephritis, eclampsia gravidarum and lead poisoning. Similar response in these conditions would add further indirect evidence that the cerebral syndrome is initiated by angiospastic phenomena.

SUMMARY AND CONCLUSIONS

Papaverine hydrochloride was administered orally to 46 patients suffering from cerebral episodes associated with hypertensive disease or cerebral vascular disease without hypertension. The drug was found to be highly effective in preventing the recurrence of seizures. The amount of papaverine necessary for optimum results was frequently three to four times the commonly accepted therapeutic dosage. In some instances 12 to 18 grains per day was required for the control of symptoms. The favorable response in our cases to papaverine is further indirect evidence that the cerebral episodes are initiated by angiospastic phenomena. Vascular encephalopathy may occur in the absence of arterial hypertension. Several illustrative cases have been reported. Trial of this drug in the encephalopathic seizures of acute glomerulonephritis, eclampsia gravidarum and lead poisoning is indicated.

ADDENDUM

Since this paper was submitted for publication 3 cases of vascular encephalopathy associated with acute glomerulonephritis were controlled successfully by large oral doses of papaverine. In addition, 2 cases of retinal angiospasm complicating hypertensive disease responded rapidly to the intravenous administration of this drug. Papaverine in adequate oral dosage was similarly effective in the treatment of a large number of cases of "hypertensive headache."

Infectious Diseases.—Of the many triumphs over human disease for which modern medicine deserves credit, perhaps none is more notable than the power to control the activity of the micro-organisms that cause infectious disease. From the time of the discovery by Pasteur of the essential relationship of bacteria to certain diseases of mankind, progress in the direction of prevention and cure has been rapid and continuous. In fact, many of the destructive plagues that in past ages brought death and disability to vast populations of the world have now entirely disappeared or become inconsequential wherever modern medical technics are understood and efficiently applied. Furthermore, such infectious diseases as are still prevalent are yielding in an almost miraculous manner to the more recent advances of medical science. Medicine finds its most appropriate field of successful activity in the stabilized populations and efficiently organized communities that progressively evolve during period of peaceful and harmonious human relations. In wartime, on the other hand, the varying disruptive influences of military conflict disturb the favorable effects of this equilibrium.—Dochez, A. R.; MacLeod, C. M., and McCormack, J. E.: Advances in Military Medicine, vol. I, Boston, Little, Brown and Company, 1948.

Clinical Notes, Suggestions and New Instruments

MASSIVE USE OF OXIDIZED GAUZE IN HEMORRHAGE FROM A MAJOR VESSEL

GEORGE A. STEWART, M. D.
and
JAMES N. CIANOS, M. D.
Baltimore

Since the preparation of oxidized gauze by Kenyon,[1] there has been an increasing use of this hemostatic agent wherever bleeding cannot be controlled by the ordinary methods of ligature or suture. Experimental work[2] in which small amounts of the material were buried in parenchymatous and supporting tissues of animals showed the gauze to be completely absorbable. There was, moreover, but slight reaction to the gauze, since there could be seen only minimal proliferation of glial and connective tissue. In no case were adhesions produced. However, when the gauze was placed in serous cavities such as the peritoneum, cysts were sometimes formed which were eventually resorbed.[3] Putnum[4] employed oxidized gauze impregnated with thrombin in thirty neurosurgical operations and reported gratifying results.

According to Frantz and associates,[3] oxidized gauze has an affinity for hemoglobin. As soon as it is soaked by blood, it turns into a brown or black mass, swells and becomes sticky. This adhering mass then effects hemostasis by taking the place of the clot that would form in the normal course of events. Reparative tissue does not invade the mass thus formed, which has a tendency to become rather friable within twenty-four hours. Healing takes place normally and the mass does not seem to be incorporated in the ensuing scar. Phagocytes which show large basophilic droplets within their cytoplasm later surround the gauze. This reaction seems to be pathognomic for oxidized gauze.

In a review of the literature, no instance could be found in which oxidized gauze was used in large quantities or in which it was used solely as a means of arresting bleeding from a major vessel. Frantz warned[3] that gauze should be used in as small a quantity as possible and also where wounds can be closed without drainage. In some instances[5] a small amount of gauze has been used in conjunction with ordinary packing and the latter was removed in twenty-four hours. In every case, however, the bleeding seems to have been a generalized ooze from raw surfaces rather than active hemorrhage from an artery or vein.

REPORT OF CASE

The patient, a white woman aged 53, was admitted to the hospital on June 22, 1947 with a diagnosis of thrombophlebitis of the left lower extremity. The present illness began suddenly on June 6, with pain in the left sural region. The pain continued to increase in severity and ascend along the leg to the groin. On the day of admission the pain was also felt in the left lower part of the abdomen and it was associated with nausea and vomiting. At about this time the leg began to swell. The remaining history was essentially negative except for a cesarean section which the patient had in 1935. This was unattended by any complications.

Physical examination showed a well nourished white woman complaining of pain in the left lower extremity. There was tenderness to deep palpation over the left lower quadrant of the abdomen. Tenderness in this region was also elicited by bimanual pelvic examination. The left lower extremity was

2. Frantz, V. K.: Ann. Surg. **118**:116, 1943.
3. Frantz, V. K.; Clarke, H. T., and Lattes, R.: Ann. Surg. **120**:181, 1944.
4. Putnum, T. J.: Ann. Surg. **118**:127, 1943.
5. Studdiford, W. E.: Am. J. Obst. & Gynec. **52**:495, 1946.

moderately edematous and of a pale cyanotic discoloration. It was cooler than the opposite extremity and exquisite tenderness was present in the region of the calf, along the course of the saphenous vein and over the femoral triangle.

The patient was placed on anticoagulants, lumbar sympathetic blocks and rest. The prothombin time was maintained at twenty-nine seconds. However, she failed to respond to this treatment, and the pain and swelling of the extremity seemed to increase. It was, consequently, decided to explore the deep veins.

With the patient under spinal "pentathol sodium" analgesia, the retroperitoneal space in the left side was exposed through a muscle-splitting incision. The peritoneum was peeled away from the posterior abdominal wall. The ureter was identified and retracted medially. The common iliac artery, which was adherent to the veins by periphlebitis, was carefully separated and retracted laterally. It was observed that the clot had ascended to the distal third of the common iliac vein, which was exposed preparatory to ligature. During this procedure a Deaver retractor which was used to retract the medial lip of the wound lacerated the common iliac vein. Immediately the field was flooded with blood. This was temporarily stopped by digital pressure and then packing. However, as soon as the pressure was removed, the vein bled just as before. Attempts to clamp the vessel merely caused it to tear proximally toward the inferior vena cava. The patient's condition was too precarious to expose and ligate the inferior vena cava through a midline incision. She was given 2,000 cc. of citrated blood and 1,000 cc. of plasma. It was decided as a last resort to pack the retroperitoneal space with oxidized gauze.[6] The contents of sixteen ampules were placed snugly against the bleeding area and held in position by a gauze pack for ten minutes. The patient's condition improved and, on removal of the pressure, it was found that there was no additional hemorrhage. The wound was quickly closed without drainage. The patient made an uneventful recovery and the wound healed per primum. Swelling and pain of the leg gradually subsided. Examination six weeks after the operation showed the wound to be well healed. There was no evidence of any mass or tenderness. The pain and swelling of the leg were completely absent and the patient stated that she experienced no difficulty.

SUMMARY

A case is reported in which massive use of oxidized gauze was used to arrest hemorrhage from a major vessel. No ill effects were observed and the gauze was apparently completely absorbed. In this particular instance enough gauze was used to act both chemically and by pressure in order to arrest bleeding.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

Austin Smith, M.D., *Secretary.*

AMINOPHYLLINE (See New and Nonofficial Remedies, 1947, p. 305).

The following dosage forms have been accepted:
George A. Breon & Co., Kansas City, Mo.

Tablets Aminophylline: 100 mg. and 200 mg.

Solution Aminophylline with Benzyl Alcohol 2%: 0.48 Gm. in 2 cc. ampuls.

Solution Aminophylline: Ampuls 0.25 Gm. in 10 cc. and 0.5 Gm. in 20 cc.

Lincoln Laboratories, Inc., Decatur, Ill.

Solution Aminophylline: 0.48 Gm. in 2 cc. and 20 cc. ampuls and 0.24 Gm. in 10 cc. ampuls.

AMINO ACID PREPARATIONS (See New and Nonofficial Remedies, 1947, p. 382).

The following dosage form has been accepted:
Mead Johnson & Company, Evansville, Ind.

Protolysate (*Powder*): 454 Gm. containers. A casein hydrolysate prepared by digestion with fish caeca for oral administration.

DIETHYLSTILBESTROL (See New and Nonofficial Remedies, 1947, p. 347).

The following dosage forms have been accepted:
Cole Chemical Co., St. Louis, Mo.

Tablets Diethylstilbestrol: 1 mg.

Solution Diethylstilbestrol in Oil: 1 cc. ampuls containing 1 mg. per cc. in peanut oil.

PHENOBARBITAL SODIUM (See New and Nonofficial Remedies, 1947, p. 418).

The following dosage form has been accepted:
The Warren-Teed Products Co., Columbus, Ohio

Solution Phenobarbital Sodium with Benzyl Alcohol 2% in Propylene Glycol: 0.13 Gm. per cc., 1 cc. ampuls.

ESTROGENIC SUBSTANCES (WATER INSOLUBLE) (See New and Nonofficial Remedies, 1947, p. 343).

The following dosage forms have been accepted:
Carroll Dunham Smith Pharmacal Co., New Brunswick, N. J.

Solution Estrusol in Oil with Benzyl Alcohol 3%: 20,000 international units per cubic centimeter in 1 cc. ampuls and 5 cc. and 15 cc. vials in peanut oil.

Solution Estrusol in Oil: 2,000, 5,000 or 10,000 international units per cubic centimeter in 1 cc. ampuls and 2,000 or 10,000 international units per cubic centimeter in 15 cc. vials in peanut oil. Preserved with 0.5 per cent chlorobutanol.

Aqueous Suspension Estrusol: 20,000 international units per cubic centimeter in 1 cc. ampuls, 5 cc. and 15 cc. vials. 1 cc. contains the equivalent of 20,000 international units of estrogenic substances, water insoluble in isotonic sodium chloride solution. Vials preserved with 0.5 per cent chlorobutanol.

THIAMINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1947, p. 506).

The following dosage form has been accepted:
Reed & Carnrick, Jersey City, N. J.

Solution Thiamine Hydrochloride: 50 mg. per cc. in 10 cc. vials. Preserved with 0.5 per cent chlorobutanol.

PENICILLIN (See New and Nonofficial Remedies, 1947, p. 144).

The following additional dosage forms have been accepted:
Premo Pharmaceutical Company, Inc., New York

Nebutabs Crystalline Penicillin G Sodium: 50,000 units of crystalline penicillin G sodium, tableted without diluent for use in the preparation of solutions for nebulization. Packaged in boxes containing 24 Nebutabs and also in packages of 12 Nebutabs with an oral nebulizer or with a nasal nebulizer.
U. S. patent applied for.

Crystalline Penicillin G Potassium in Oil and Wax: 300,000 units per cubic centimeter, 5 cc. and 10 cc. vials. Penicillin G potassium suspended in peanut oil containing 4.8 per cent (W/V) white wax, U. S. P.

STREPTOMYCIN (See New and Nonofficial Remedies, 1947, p. 150).

The following dosage form has been accepted:
E. R. Squibb & Sons, New York

Streptomycin Hydrochloride: 20 cc. vials containing streptomycin hydrochloride equivalent in activity to 1 Gm. of streptomycin base and 40 cc. vials containing streptomycin hydrochloride equivalent in activity to 2 Gm. of streptomycin base.

EDITORIAL ANNOUNCEMENT

The absence of the compositors employed by the American Medical Association from their work continues. This issue of THE JOURNAL has been prepared largely by the use of Vari-Typer machines. Because of the difficulties of reorganization of the headquarters office necessitated by this situation, the editorial material in this issue of THE JOURNAL has been greatly condensed.

HEPATIC CIRRHOSIS TREATED WITH METHIONINE

In January 1947 the Council on Pharmacy and Chemistry reported on the status of methionine in the prevention and treatment of injury to the liver.[1] Certain chemical agents produced lesions in the liver of experimental animals closely resembling those seen in man in portal cirrhosis. Much experimental evidence is available indicating that injury of the liver may be produced by dietary deficiencies. Gyorgy and Goldblatt[2] found that necrosis or cirrhosis of the liver would develop in rats on a low protein diet and that the administration of choline would prevent the development of these conditions. Daft, Sebrell and Lillie[3] confirmed this work and found also that some protection to the liver was afforded by the addition of choline, methionine and casein. In a later report[4] Gyorgy and Goldblatt concluded that the cirrhosis produced in animals by a low protein diet could be prevented by a combination of choline and cystine or by methionine alone. The Council in its report emphasized, however, that the experimental dietary cirrhosis seen in animals is not histologically the same as portal cirrhosis in man and that the experiments need clinical confirmation on human patients.

Since the Council's report was published a study on a group of patients with cirrhosis has been reported[5] by Beams and Endicott. Nine patients with cirrhosis in the decompensated stage were given dl-methionine by mouth; 3 patients who were extremely ill first received a 2 per cent solution of the agent by vein from eight to twenty days preceding the oral administration. All patients in this group were given a high protein, low fat diet and 45 Gm. of brewers' yeast a day, except 1 patient who was not able to take so much protein and yeast. All except 1 patient received also 5 cc. of crude liver extract three times a week. A second group of 5 patients, including 2 who had been treated with methionine supplement and had had recurrences, received the same treatment as the first group except for methionine supplement. The food intake of most of both groups was calculated daily. The diet provided from 2 to 5 Gm. of methionine a day. Liver needle biopsies were obtained before treatment started and again after periods of several weeks of treatment. Other laboratory studies were done at frequent intervals.

The 9 patients who received methionine supplement showed histologic changes in the liver which indicated a favorable response to the treatment; 5 patients in this group, 1 of whom did not receive crude liver extract, showed clinical improvement also, and 3 of them have remained well for from one to two years. Two of the 5 patients ate poorly, continued to drink intoxicating liquor after discharge from the hospital and had recurrences, 1 after twelve months and 1 after seven months.

While the histologic changes in the liver indicating favorable response to treatment occurred in both groups of patients, a definite difference was observed in the number of patients who showed such changes and in the degree of change. In those who received methionine supplement the changes were striking. The parenchymal cells revealed definite improvement in histologic appearance, and there was a disappearance of fat. The only difference in the treatment of the two groups was the use of methionine supplement. The author concludes, therefore, that methionine was responsible for the different results obtained.

---

[1] The Status of Methionine in the Prevention and Treatment of Liver Injury, report of the Council on Pharmacy and Chemistry, J.A.M.A. 133:107 (Jan. 11) 1947.

[3] Daft, F.S.; Sebrell, W.H., and Lillie, R.D.: Proc. Soc. Exper. Biol. & Med. 48:228-229, 1941.

[4] Gyorgy, P., and Goldblatt, H.: J. Exper. Med. 75:191-195, 1942.

[5] Beams, A.J., and Endicott, E.T.: Gastroenterology 9:718-735, 1947

In one half of the cases the improved histologic picture was accompanied by improvement in the clinical course and, in some, of the liver function tests also. An increase in sulfobromophthalein sodium excretion was a fairly constant observation. In the other half of the cases no correlation was noted between the histologic changes and the clinical course or hepatic function. Two patients improved clinically but did not show histologic changes, and 1 of them did not show improved function of the liver. An adequate explanation is not available for the correlation between the histologic changes, laboratory results and clinical course in some patients and not in others. Possible in those who showed an improved histologic picture without improvement in the clinical or laboratory observations the perilobular fibrosis isolated hepatic lobules or groups of cells in a manner that interfered with the portal circulation and obstructed the biliary capillaries.

Thus all the patients who received the methionine supplement showed histologic changes indicating a favorable response irrespective of a high protein diet, crude liver extract or brewers' yeast. Among the patients who did not receive methionine supplement only 1 showed significant histologic changes after treatment. Clinical improvement and improvement in hepatic function were associated with histologic changes in 7 patients, 6 of whom received methionine supplement and 1 of whom did not.

This study suggests that methionine was responsible for the improved histologic changes in the liver which occurred in these patients.

Current Comment

THE WORLD HEALTH ORGANIZATION

Recently the Rules Committee of the House of Representatives tabled a bill to ratify the constitution of the World Health Organization and make the United States a member of that body. Already twenty-three other nations have signed the constitution of W.H.O., and the three additional ratifications necessary to complete organization will unquestionably become effective within the next few weeks. The first meeting of the new World Health Organization has been called in Geneva, Switzerland, in June 1948. This means, no doubt, that the United States will not be present as a member. Unfortunately a statement has not appeared as to why the Rules Committee took the action mentioned. Unless there are reasons which are secret and not available, the failure of the Rules Committee to recommend positive action is an embarrassment to American leaders in the field of health. The American Medical Association has thus far participated in the development of the World Health Organization and has also played a leading role in the organization of the World Medical Association. There has seemed to be every reason why these two bodies could cooperate for the advancement of world health. Some of the projects which the Interim Commission of the World Health Organization has been studying include international agreements for the control of quarantine and isolation and for the prevention and spread of infectious diseases; the establishment of international standards for biologic and similar agents, and the development and circulation of scientifically collected vital statistics. The Rules Committee which has rejected participation by the United States in this activity would do well to explain the action taken to the American agencies interested in public health which have thus far strongly supported participation by our government in the World Health Organization.

PRESCRIBING OF PHARMACEUTIC SPECIALTIES

At a recent meeting, the Council on Pharmacy and Chemistry considered complaints from physicians who wished to incorporate some of the newer drugs in their prescriptions. These could not be filled readily because of the unavailability of the product in bulk forms. These physicians requested the Council to require manufacturers to supply their drugs in bulk form before consideration would be given to the product for inclusion in New and Nonofficial remedies. The Council did not consider it feasible to make such a requirement but expressed the opinion that pharmaceutic manufacturers should be informed of the desirability of making drugs available in powdered or bulk form. The growing tendency to make all drugs available in ready-made dosage forms has been the result of a number of factors. Economy, accuracy in dosage and pharmaceutic elegance are among the immediate reasons. The development of new potent or specific remedies and the decline of polypharmacy are among the more basic reasons for this trend. The result of this trend has tended to diminish the individualization of therapy. The treatment of disease is only one aspect of the treatment of the patient. The therapy prescribed should be designed to fit the needs of the individual patient and not the "average" patient. Rational combinations of drugs are required on occasion as well as dosages not available from the stocks of a commercial supplier. If the drugs are not available in bulk form, the pharmacist either cannot fill the prescription or must laboriously convert one dosage form into another.

ORGANIZATION SECTION

Washington Letter

(From a Special Correspondent)

April 2 1948.

Congress Studies Military Training and Draft Legislation

Congress has under consideration the recommendations of President Truman for expanded defense forces, and enactment of universal military training and the draft. The armed services have submitted to the President alternate defense plans calling for from $2,000,000 to $11,000,000 more than the proposed $11,000,000,000 military budget for fiscal 1949. Testifying before the Senate Armed Services Committee, Dr. Karl T. Compton, president of Massachusetts Institute of Technology, declared that some educational groups and educators were hasty and ill-informed in opposing a training program. On the question of reestablishing the draft, the American Veterans of World War II have recommended that disabled veterans of 1941-45 be given key posts on selective service boards. Republican senators have indicated that they might consent to register, but delay the drafting of, young men for military service.

Only Twenty-Eight Doctors Accused of Overcharging Veterans

Although there are in the United States about 85,000 physicians authorized to give veterans hometown treatment on the basis of billing the Veterans Administration for the expense under a set schedule of fees, only twenty-eight physicians have been accused by the agency of irregularities. Their names have been given to the American Medical Association, the agency reported. Alleged offenses range from minor violations of regulations to fraud. One physician is accused of charging the agency $160 for treatment of a veteran and of billing the same treatment for another $100. Names of the physicians were not disclosed. Of twenty removed from the authorized lists, five were in the New York region, four in Philadelphia, four in Pittsburgh, three in Chicago, and one each in Norfolk, Va.; Minneapolis, Wichita, Kan., and San Francisco.

Criticism of Condon Described as Threat to Research

Dr. David R. Inglis, Johns Hopkins University physicist and a former member of the Los Alamos atomic energy laboratory, told a meeting of the Washington Association of Scientists that the action of a House Committee in questioning the loyalty of Dr. Edward U. Condon, director of the National Bureau of Standards, was a threat to scientists and scientific research. He said: "There are large implications to these attacks; first, those pertaining to science and scientists—the contributions of scientists to the national welfare—and, second, those pertaining to the constitutional liberties of all citizens." With reference to the vast program of governmental research, he said that such technics of character assassination mean that scientists and engineers will "be very reluctant to enter federal research agencies." He added that 'the witch hunt might even be extended to embrace all scientists as a class."

St. Elizabeths Hospital

Dr. Winfred Overholser, superintendent of St. Elizabeths Hospital, stated in his annual report, forwarded to Congress by Federal Security Administrator Oscar R. Ewing, that dangerous mental patients are kept in an inadequate building which should be replaced by a new four hundred bed security unit. He said that limited space made it necessary to keep dangerously aroused patients and those under criminal charges in a building which was built more than thirty years ago.

George Washington University Hospital Opened to Public

The public and press of the capital accorded a *cordial 'welcome" to newly opened four hundred* bed George Washington University Hospital. The $4,000,000 structure is the first of several buildings that the university plans to have in its medical center. The modern character of the hospital impressed visitors.

State Legislation

Kentucky

Bill Introduced.—H. 424, relating to hospitals, proposes that no hospital shall deny admission to the patient of *any licensed physician at any time that there are in the* hospital beds and room facilities suitable for such patient and further proposes that no hospital shall enter into any agreement with any physician or group of physicians pursuant to which any bed or room facilities in the hospital are to be reserved for unnamed patients of such physicians or pursuant to which such physicians are allocated or assigned certain bed or room facilities for their patients.

Bills Passed.—H. 447 passed the senate March 19. It authorizes any hospital or other institution offering accredited courses of instruction in nursing, medicine, surgery, or other related courses of graduate study or on the professional level, to elect by a majority vote of its governing body to receive as pupils persons of all races. S. 105 passed the house March 10. It proposes the creation of a medical research commission to provide for a program of research in the fields of medicine, surgery and allied sciences, preventive medicine, control of diseases and all other features of medicine and surgery that affect the health and welfare of the people of the state. S. 197 passed the house March 18. It proposes the creation and establishment of a division of medical hospitals and related *services in the department of health to* make a survey of hospital facilities throughout the state and to accept federal funds to assist in the construction of additional needed facilities. The proposal would also require the appointment of an advisory council and the preparation of necessary regulations and standards pertaining to the conduct and operation of hospitals which are constructed by virtue of the act. S. 342 passed the house March 19. It proposes to create a Kentucky Building Commission to have charge of buildings constructed throughout the state and proposes that appropriations to this commission shall be used, among other things, for matching funds for hospital construction under any law now existing or that may be passed by the national Congress.

Mississippi

Bills Introduced.—H. 687 proposes the enactment of a hospital licensing law and, in conjunction therewith, the appointment of an advisory hospital council to consult and advise with the licensing agency and to assist in the development of rules, regulations and standards to be required of hospitals seeking licensure. H. 717 proposes an *appropriation to defray the expenses of the* state program of eradication and control of syphilis and other venereal diseases. H. 818 proposes an appropriation to the Mississippi commission on hospital care for the purpose of building, erecting and equipping hospitals and other facilities within the state of Mississippi. S. 453 proposes an enabling act for the organization and operation of nonprofit hospital, medical and surgical service corporations.

Coming Medical Meetings

Alabama, Medical Association of the State of, Mobile, April 15-17. Dr. D. L. Cannon, 519 Dexter Ave., Montgomery 4, Secretary.

American Association for the Study of Goiter, Toronto, Can., King Edward Hotel, May 6-8. Dr. Thomas C. Davison, 478 Peachtree St.N.E., Atlanta, Ga., Secretary.

American Association of Anatomists, Madison, Wis., April 21-23. Dr. Normand L. Hoerr, 2109 Adelbert Road, Cleveland 6, Secretary.

American Association of Genito-Urinary Surgeons, Skytop, Pa., Skytop Lodge, May 12-14. Dr. Norris J. Heckel, 122 S. Michigan Ave., Chicago 3, Secretary.

American Association of Plastic Surgeons, Boston, May 6-8. Dr. W. H. Steffensen, 1810 Wealthy St.S.E., Grand Rapids, Mich., Secretary.

American Association of the History of Medicine, Philadelphia, Penn Sheraton Hotel, May 26-27. Dr. Howard Dittrick, 2020 E. 93d St., Cleveland 6, Secretary.

American Association on Mental Deficiency, Boston, Hotel Statler, May 12-15. Dr. Neil A. Dayton, Box 51, Mansfield Depot, Conn., Secretary.

American Broncho-Esophagological Association, Atlantic City, Chalfonte-Haddon Hall, April 7-8. Dr. Paul H. Holinger, 700 N. Michigan Ave., Chicago 11, Secretary.

American College of Physicians, San Francisco Civic Auditorium, April 19-23. Mr. E. R. Loveland, 4200 Pine St., Philadelphia 4, Secretary.

American Dermatological Association, Coronado, Calif., April 26-29. Dr. Harry R. Foerster, 208 E. Wisconsin Ave., Milwaukee, Secretary.

American Federation for Clinical Research, Atlantic City May 4. Dr. John S. LaDue, 139 E. 36th St., New York 16, Secretary.

American Gastro-Enterological Association, Atlantic City, Claridge Hotel, April 30-May 1. Dr. Dwight L. Wilbur, 655 Sutter St., San Francisco, Secretary.

American Hearing Society, Pittsburgh, May 19-23. Mrs. Frances E. Lee, 817 Fourteenth St. N.W., Washington 5, D. C., Secretary.

American Laryngological Association, Hot Springs, Va., April 14-15. Dr. Louis H. Clerf, 1530 Locust St., Philadelphia 2, Secretary.

American Laryngological, Rhinological and Otological Society, Atlantic City, April 7-9. Dr. C. Stewart Nash, 277 Alexander St., Rochester, N. Y., Secretary.

American Ophthalmological Society, Hot Springs, Va., May 16-19. Dr. Walter S. Atkinson, 129 Clinton St., Watertown, N. Y., Secretary.

American Orthopsychiatric Association, New York, Hotel Commodore, April 12-14. Nina Ridenour, Ph.D., 1790 Broadway, Rm. 916, New York 19, Secretary.

American Otological Society, Hot Springs, Va., April 12-13. Dr. Gordon D. Hoople, 713 E. Genesee St., Syracuse 2, N. Y., Secretary.

American Pediatric Society, Quebec, Can., May 24-26. Dr. Henry G. Poncher, 1819 W. Polk St., Chicago 12, Secretary.

American Physiotherapy Association, Chicago, La Salle Hotel, May 23-28. Miss Mildred Elson, 1790 Broadway, New York 19, Executive Secretary.

American Psychiatric Association, Washington, D. C., Statler Hotel, May 17-20. Dr. Leo H. Bartemeier, General Motors Bldg., Detroit 2, Secretary.

American Society for Clinical Investigation, Atlantic City, Haddon Hall, May 3. Dr. Eugene A. Stead Jr., Duke Hospital, Durham, N. C., Secretary.

American Society for Research in Psychosomatic Problems, Atlantic City, May 1-2. Dr. Eugene Ferris, 714 Madison Ave., New York 21, Secretary.

American Student Health Association, Detroit, Hotel Statler, May 7-8. Dr. George T. Blydenburgh, Ohio Weslayan University, Delaware, Ohio, Secretary.

American Urological Association, Boston, Hotel Statler, May 17-20. Dr. Thomas D. Moore, 899 Madison Ave., Memphis 3, Tenn., Secretary.

Arizona State Medical Association, Phoenix, Hotel Westward Ho, May 19-21. Dr. Frank J. Milloy, 234 N. Central Ave., Phoenix, Secretary.

Arkansas Medical Society, Little Rock, Robinson Auditorium, April 15-17. Dr. W. R. Brooksher, 602 Garrison Ave., Fort Smith, Secretary.

Association of American Physicians, Atlantic City, May 4-5. Dr. Henry M. Thomas Jr., 1201 N. Calvert St., Baltimore 2, Secretary.

California Medical Association, San Francisco, April 11-14. Dr. L. Henry Garland, 450 Sutter St., San Francisco 8, Secretary.

Connecticut State Medical Society, Fairfield, April 27-29. Dr. Creighton Barker, 258 Church Street, New Haven, Secretary.

Florida Medical Association, St. Augustine, Ponce de Leon Hotel, April 11-14. Dr. Robert B. McIver, 111 W. Adams St., Jacksonville, Secretary.

Georgia, Medical Association of, Atlanta, April 27-30. Dr. Edgar D. Shanks, 478 Peachtree St. N.E., Atlanta Secretary.

Hawaii Territorial Medical Association, Honolulu, May 6-9. Dr. Harry L. Arnold Jr., 510 S. Beretania St., Honolulu 53, Secretary.

Illinois State Medical Society, Chicago, Palmer House, May 10-12. Dr. Harold M. Camp, 224 S. Main St., Monmouth, Secretary.

International Congresses on Tropical Medicine and Malaria, Washington, D.C., May 10-18. Dr. Wilbur A. Sawyer, Department of State, Washington 25, D.C., Executive Secretary.

Iowa State Medical Society, Des Moines, April 18-21. Dr. John C. Parsons, 406 Sixth Ave., Des Moines 9, Secretary.

Kansas Medical Society, Wichita, The Forum, May 10-13. Dr. Dale D. Vermillion, 512 New England Bldg., Topeka, Secretary.

Louisiana State Medical Society, Monroe, April 12-14. Dr. P. T. Talbot, 1430 Tulane Ave., New Orleans 13, Secretary.

Maryland, Medical and Chirurgical Faculty of the State of, Baltimore, April 27-28. Dr. George H. Yeager, 1211 Cathedral St., Baltimore, Secretary.

Massachusetts Medical Society, Boston, Hotel Statler, May 25-27. Dr. H. Quimby Gallupe, 8 Fenway, Boston 15, Secretary.

Mississippi State Medical Association, Jackson, May 11-13. Dr. T. M. Dye, Box 295, Clarksdale, Secretary.

National Society for the Prevention of Blindness, Minneapolis, Hotel Radisson, April 5-7. Mrs. Eleanor Brown Merrill, 1790 Broadway, New York 19, Executive Director.

Nebraska State Medical Adsociation, Lincoln, Hotel Cornhusker, May 3-6. Dr. R. B. Adams, 416 Federal Securities Bldg., Lincoln 8, Secretary.

New England Dermatological Society, Boston, April 14. Dr. G. Marshall Crawford, 1180 Beacon St., Brookline, Secretary.

New Jersey, Medical Society of Atlantic City, Haddon Hall, April 26-29. Dr. Earl LeRoy Wood, 315 W. State St., Trenton, Secretary.

North Carolina, Medical Society of the State of. Pinehurst, May 3-5. Dr. Roscoe D. McMillan, P.O. Box 232, Red Springs, Secretary.

North Dakota State Medical Association, Jamestown, May 23-28. Dr. O. A. Sedlak, 792 First Ave. S., Fargo, Secretary.

Northern Tri-State Medical Association, Findlay, Ohio, April 14. Dr. F. Cameron, 247 W. Berry St., Fort Wayne, Indiana, Secretary.

Ohio State Medical Association, Cincinnati, Netherland Plaza Hotel, March 30-April 1. Mr. C. S. Nelson, 79 E. State St., Columbus 15, Secretary.

Oklahoma State Medical Association, Oklahoma City, Skirvin Hotel, May 17-19. Mr. R. H. Graham, 210 Plaza Court, Oklahoma City, Executive Secretary.

Post Graduate Institute of the Philadelphia County Medical Society, Philadelphia, Bellevue-Stratford Hotel, April 20-23. Dr. Gilson Colby Engel, 301 S. 21st St., Philadelphia, Director.

Rhode Island Medical Society, Providence, May 12-13. Dr. Morgan Cutts, 106 Francis St., Providence 3, Secretary.

Society of American Bacteriologists, Minneapolis, Nicollet Hotel, May 10-14. Dr. Leland W. Parr, 1335 H St. N. W., Washington 5, D. C., Secretary.

Society of Biological Psychiatry, Washington, D.C., May 16. Dr. George N. Thompson, 1136 W. Sixth St., Los Angeles 14, Secretary.

South Carolina Medical Association, Charleston, Francis Marion Hotel, May 12-14. Dr. Julian P. Price, 105 W. Cheves St., Florence, Secretary.

Southeastern Surgical Congress, Hollywood, Fla., Hollywood Beach Hotel, April 5-8. Dr. Benjamin T. Beasley, 45 Edgewood Avenue S.E., Atlanta 3, Ga., Secretary.

Southern Society of Clinical Surgeons, Chicago, May 26-28. Dr. William P. Nicolson Jr., 478 Peachtree St. N.E., Atlanta, Ga., Secretary.

Southwest Allergy Forum, Oklahoma City, April 5-6. Dr. Fannie Lou Leney, 1200 N. Walker St., Oklahoma City, Secretary.

Tennessee State Medical Association, Nashville, April 13-14. Dr. W. M. Hardy, 706 Church St. Nashville 3-Secretary.

Texas, State Medical Association of, Houston, Rice Hotel, April 26-29. Dr. Harold M. Williams, 1404 W. El Paso St., Fort Worth, Secretary.

Western Association of Industrial Physicians and Surgeons, San Francisco, Fairmont Hotel, April 10. Dr. Christopher Leggo, Crockett, Calif. Secretary.

Western Section American Urological Association, Victoria, B. C., Empress Hotel, April 19-21. Dr. Adolph A. Kutzmann, 1930 Wilshire Blvd., Los Angeles, Secretary.

GOVERNMENT SERVICES

ARMY

MODIFICATION OF THE MUNSON SHOE LAST

The Army's service and combat footwear has been made over the Munson last since 1912. Brig. Gen. Edward L. Munson, of the Army Medical Corps, then a lieutenant colonel, designed the last after the most comprehensive study of the human foot in relation to military footwear ever undertaken by the Army up to that time. The Munson last served American soldiers in two great wars and at the time of its development was the most scientific approach ever made to properly fitting the soldier's foot. However, World War II demonstrated that the shoes and boots fitted too closely over the little toe area and wore out too quickly because of the excessive roundness of the bottom forepart of the last. To overcome these deficiencies, the last has now been modified to allow 1/8 inch (0.3 cm.) more room in the forepart of the shoe and to reduce the roundness of the bottom forepart across the tread.

Modification of the Munson last is only an interim step in a long range project which contemplates a completely new last. Two major surveys have determined the actual shapes and measurements of men's feet representing the Army as a whole. One, conducted by the Army Medical Research Laboratory at Fort Knox, covered twenty-seven different foot measurements of 7,559 men. The other survey of nearly 100,000 men at separation centers was a part of an anthropometric survey conducted by the Quartermaster Corps.

During and since the war the Quartermaster Corps has supplied two hundred and thirty-nine different sizes of footwear in regular and special sizes, besides other sizes made to special measurements. There are ninety sizes in the regular footwear tariff. The one hundred and forty-nine special sizes covered men who could not be fitted in the regular tariff.

CHIEF DIETITIAN MADE A LIEUTENANT COLONEL

The Surgeon General announced February 24 the appointment of Major Helen C. Burns as assistant director of the new Women's Medical Corps and chief of the dietitian section of that corps, with the rank of Lieutenant Colonel, the highest grade yet held by an Army dietitian. Colonel Burns is a graduate of Simmons College, Boston, and attended the Army School for Dietitions at Walter Reed General Hospital. She was superintendent of dietitians in the Surgeon General's Office during the recent war and is a past president of the District of Columbia Dietetic Association.

AWARDS AND COMMENDATIONS

Colonel Montgomery E. Leary

The Army Commendation Ribbon has been awarded to Col. Montgomery E. Leary, M.C., O.R.C., of Rochester, N. Y. The citation reads as follows: "Colonel Montgomery E. Leary performed meritorious service as Contract Surgeon for the United States Army at Rochester, N. Y., from June 1943 to May 1945. Despite difficulties as to equipment, transportation, supplies and drugs necessary for the treatment of personnel at military installations in Rochester and the vicinity for whose care he was responsible, he displayed outstanding devotion to duty and loyalty in providing them with proper medical treatment and attention." Colonel Leary was graduated from the University of Pennsylvania Medical School and was called to active duty as medical officer in charge of medical care of personnel in the Rochester area June 1, 1943.

NAVY

APPROVED FOR POSTGRADUATE TRAINING

The Advisory Board of the Bureau of Medicine and Surgery has approved the following officers for postgraduate training:

Lieut. Frank H. Thomas Jr. (MC); course in internal medicine at the University of Pennsylvania Graduate School of Medicine.

Comdr. Henry J. Hunter (MC); obstetrics and gynecology at the Boston Lying-In Hospital and the Free Hospital for Women, Brookline, Mass.

Comdr. Clement D. Burroughs (MC); residency in ophthalmology at a Naval Hospital.

Lieut. (jg) Earl E. Correll (MC); residency in otolaryngology at the Naval Hospital, San Diego, Calif.

Lieut. David J. McMurray (MC); residency in otolaryngology at a Naval Hospital.

Lieut. (jg) Fred A. Valusek (MC); residency in otolaryngology at a Naval Hospital.

Lieut. (jg) Newman A. Hoopingarner (MC); residency in orthopedic surgery at Naval Hospital, St. Albans, L.I., N.Y.

Comdr. Richard B. Williams Jr. (MC); instruction in pathology and research at University of Pennsylvania.

Comdr. Neville C. Bowers (MC); additional years' training in psychiatry at National Naval Medical Center, Bethesda, Md.

Comdr. David P. Hightower (MC); additional years training in psychiatry at the Naval Hospital National Naval Medical Center, Bethesda, Md.

TRANSFER RESEARCH UNIT

The naval hospital at Dublin having been turned over to the Veterans Administration, plans are under way to transfer Naval Medical Research Unit 4 from that hospital to the Naval Training Station at Great Lakes, Illinois.

NAVY AWARDS AND COMMENDATIONS

Jacob C. Geiger, M.D.

The U.S. Navy, through the Surgeon General, has awarded a certificate of appreciation to Dr. J.C. Geiger, director of public health of San Francisco. The citation read as follows: "In grateful acknowledgment of exceptional and outstanding services rendered to the Medical Department of the Navy during the period of World War II." A special citation from the District Medical Officer of the Twelfth Naval District read: "For meritorious services in the control of communicable diseases in the port of San Francisco." Dr. Geiger graduated from Tulane University of Louisiana School of Medicine, New Orleans in 1912.

VETERANS ADMINISTRATION

PATIENTS WITH NONSERVICE-CONNECTED DISABILITIES

In a statistical summary of Veterans Administration activities as of Jan. 3, 1948, the number of patients in hospitals was 109,018, of whom 94,948 were in veterans' hospitals. Of these, 62,384 were veterans with nonservice-connected disabilities and 31,297 were veterans with service-connected disabilities. Of the patients in other than veterans' hospitals, 8,085 were veterans with nonservice-connected disabilities and 5,953 were veterans with service-connected disabilities. In addition there were 14,920 beneficiaries in Veterans Administration homes. The number of veterans awaiting hospital admission at the end of the month was 19,505, of whom 18,907 had nonservice-connected disabilities.

NEW CHIEF OF NEUROPSYCHIATRIC SERVICE

Dr. Paul B. Magnuson, chief medical director of the Veterans Administration, has announced the appointment of Dr. Harvey J. Tompkins of Arlington, Va., as head of the neuropsychiatric service in the department of medicine and surgery to succeed Dr. Daniel Blain, who resigned to become medical director of the American Psychiatric Association. Dr. Tompkins graduated in medicine at Loyola University of Chicago. He joined the Veterans Administration in 1935 and, after serving at hospitals in various states, was assigned to the central office in 1945 as assistant chief of the neuropsychiatry division. He is associate professor in psychiatry at Georgetown University School of Medicine and is certified by the American Board of Psychiatry and Neurology.

PERSONAL

Dr. Lee G. Sewall has been appointed chief of professional services at the Roanoke (Va.) veterans' hospital and Dr. Victor J. Covalesky, as assistant chief.

Dr. Carroll L. Moore has become manager of the veterans' hospital at Excelsior Springs, Mo., succeeding Dr. S. E. Walker, who has been transferred to the regional office in Kansas City, Mo.

Dr. Peter A. Volpe, Worthington, Ohio, has been appointed medical director for the Veterans Administration for Ohio, Michigan and Kentucky. Dr. Volpe served in the recent war with the Sixth Armored Division.

MISCELLANEOUS

RADIOACTIVE ISOTOPES GO TO FOREIGN COUNTRIES

The United States atomic energy commission has disclosed according to *Chicago Tribune*, that forty-four shipments of radioactive isotopes have been sent to individuals and research groups in eight countries since the foreign distribution program was announced last September. Since then, sixteen countries have completed arrangements for receiving radioactive isotopes for medical and biologic research from Oak Ridge, Tenn. These countries are Argentina, Australia, Belgium, Canada, Cuba, Denmark, France, Ireland, Italy, Netherlands, New Zealand, Peru, South Africa, Switzerland and the United Kingdom. Radioactive phosphorus has been exported more than any other of the isotopes available.

Any country desiring radioactive isotopes must first submit to the state department the name of its representative in the United States who will maintain liason with the Atomic Energy Commission. The applicant country agrees to forward to the commission progress reports at intervals of six months on the results of the investigations carried on with the isotopes and agrees that the material will not be used for purposes other than those shown in the request.

ATOMIC ENERGY FELLOWSHIP TRAINING PROGRAM

The U. S. Atomic Energy Commission announces a fellowship program for training qualified persons for careers in the medical and biologic aspects of atomic energy. The commission will finance the program and establish the operating policies and training goals to be met; actual administration of the program, including selection of candidates, will be undertaken on behalf of the commission by the National Research Council, which has had broad experience in the administration of fellowship programs. Announcements concerning number of fellowships to be offered, stipends and qualifications of candidates and conditions of the awards will be issued through the National Research Council in the near future.

Applicants from any branch of biology or medicine are eligible for fellowships. At present, candidates will be favored who intend to follow a career of research in one of the basic biologic or medical sciences as related to the field of atomic energy or in clinical medicine or surgery as related to the field of atomic energy. Applicants in medicine and surgery will be encouraged to lay out a program of study leading to thorough experience in a preclinical science during which study they become identified with this science as such and not primarily with its application to clinical studies.

The initial fellowships will be distributed among three broad classes of candidates, including (1) doctors of medicine; (2) doctors of philosophy in the biologic sciences and (3) bachelors of science and of arts, who will receive training in health physics. Postdoctoral fellowships will extend for a period of two years with annual stipends, depending on marital status, commensurate with other fellowship programs. Graduate training in health physics will extend for a period of one year or longer, depending on the qualifications of the candidate and his need or desire for additional training.

It is anticipated that fellows trained under the program will become leaders in future development of medical and biologic education in the field of atomic energy. An opportunity to use their training at research and production centers will be offered, although the fellows will not be committed to work at installations of the Atomic Energy Commission following their training.

Special consideration will be given institutions in which it is possible to integrate medical and biologic training with physics, chemistry and mathematics. Since conditions allowing this combination are limited, special facilities are being provided at A. E. C. regional laboratories and at certain universities. However, fellowship training will not be limited to these institutions. As a rule a fellow will be requested to work in an institution other than that to which he is attached at the time of application or at which he has done most of his postgraduate work.

A paramount factor in planning the size and scope of the fellowship program was the serious shortage of trained scientific personnel in the field of atomic energy as applied to biology and medicine.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

ALABAMA

First Annual Graves Lectures. —An annual lecture series honoring Dean Stuart Graves, director of admissions for medicine at the Medical College of Alabama, Birmingham, and dean of the school from 1928 to 1945, was initiated at the Jefferson-Hillman auditorium recently, sponsored by the Nu Sigma Nu Fraternity. Dr. E. Thompson Bell, director since 1921, department of pathology, University of Minnesota Medical School, Minneapolis, was the speaker. Dr. Graves has been a national officer of the Nu Sigma Nu Fraternity for more than forty years.

ARIZONA

Society News. —Dr. Charles N. Sarlin, Tucson, read a paper on "The Dissection of a Neurotic Personality" before the Arizona Society of Psychiatry and Neurology February 28.

Foods Manufacturer Fined.—A federal court jury February 20 found Adolphus Hohensee, lecturer on health and manufacturer of "Adolphus" brand foods and drugs, guilty on twenty-one of twenty-two counts charging misbranding of "health" products shipped in interstate commerce, according to newspaper reports. He was fined $1,800 and was not committed. Hohensee, a native of Scranton, Pa., had been lecturing in Phoenix.

CALIFORNIA

Popular Medical Lectures.—Stanford University School of Medicine, San Francisco, is presenting the sixty-sixth course of lectures at Lane Hall on Friday evenings at 8 o'clock. Three more lectures will be given: April 9, Drs. Roland A. Davison, Donald E. King and William H. Northway, all of San Francisco, "Rheumatism: the Great Crippler"; April 16, Dr. William M. M. Kirby, San Francisco, "Can Streptomycin Cure Tuberculosis?" and April 30, Dr. Edwin H. Lennette, Berkeley, "Filtrable Viruses: the Invisible Killers."

State Medical Meeting.—The annual session of the California Medical Association will be held in San Francisco with headquarters at the St. Francis Hotel April 11-14, under the presidency of Dr. John W. Cline, San Francisco. Guest speakers at the general sessions will be:

George F. Lull, Chicago, Secretary and General Manager, American Medical Association, What is Being Done About the Ten Point Program?
Richard B. Cattell, Boston, Carcinoma of the Rectum.
J. William Hinton, New York, End Result of Thorocolumbar Sympathectomy in Advanced Essential Hypertension.
Wesley Bourne, Montreal, Canada, Anesthesiology.
George W. Thorn, Boston, Diagnosis and Treatment of Adrenal Insufficiency.
Henry E. Michelson, Minneapolis, Dermatology.

A clinical-pathologic conference is scheduled for part of the Tuesday morning program, and special meeting on postgraduate training and medical economics will be held Wednesday from 2 to 4 p.m. Sectional meetings have been arranged on general surgery; general practice; anesthesiology; dermatology and syphilology; eye, ear, nose and throat; industrial medicine and surgery; neuropsychiatry; obstetrics and gynecology; pathology and bacteriology; pediatrics; public health; radiology, and urology. The Woman's Auxiliary will meet April 11-13 at the Mark Hopkins Hotel. The California Heart Association, the California Society of Internal Medicine and the Western Association of Industrial Physicians and Surgeons will hold annual meetings in conjunction with that of the medical association.

COLORADO

Course in Well Child Supervision.—The Colorado State Department of Health, the Rocky Mountain Pediatric Society and the University of Colorado Medical Center will sponsor a three day graduate course in well child supervision at the University of Colorado Medical Center, Denver, April 26-28. The course is intended primarily for Colorado physicians, but other physicians who are interested may apply in writing to the director of graduate medical education, Dr. Frode Jensen, University of Colorado Medical Center, 4200 East Ninth Avenue, Denver 7.

ILLINOIS

Meeting of Chest Physicians.—The Illinois Chapter of the American College of Chest Physicians will meet April 16 at 8 p.m. in the Congress Hotel, Chicago. Subjects to be discussed are "Bronchial Lavage as a Diagnostic Aid in Chest Diseases" and "Differential Diagnosis in Cystic Disease of the Lung." A panel discussion on adenoma of the bronchus completes the program. A dinner has been arranged at the hotel for 6:39 p.m., and all physicians are invited.

Chicago

Cancer Research Grants.—Grants totaling $325,547 for cancer research have been given to the University of Chicago and six individual medical investigators by the American Cancer Society, Inc. A check for $190,000 was received February 27 at the annual meeting of the cancer society in Chicago.

City Gets Third Cancer Detection Center.—The third cancer detection center for the city of Chicago was opened at Grant Hospital on March 12, under the sponsorship of the American Cancer Society Inc. Only women patients will be admitted. Other centers previously opened are at Women's and Children's Hospital and at Henrotin Hospital.

Kretschmer Memorial Lecture.—The seventh Edwin R. Kretschmer Memorial Lecture will be delivered at the Palmer House Friday evening, April 23, at 8 o'clock by Julius White, Ph.D., head chemist, U.S. Public Health Service, National Institute of Health, Bethesda, Md., on "Experimental Studies on Leukemia in Mice."

Northwestern Faculty-Alumni Reunion.—The annual Faculty-Alumni Reunion Dinner will be held May 8 at the Furniture Club of America, 666 Lake Shore Drive, Chicago, at 6 p.m. The cost of the dinner is $6 a plate, and reservations must be made not later than May 4 at the Medical Alumni Office, 303 East Chicago Avenue, Chicago, Room 796. The telephone number is Superior 4500. The five year classes of 1903, 1908, 1913, 1918, 1923, 1928, 1933, 1938 and 1943 should plan special reunions. The honored guests will be the fifty and fifty-five year classes, 1898 and 1893, and the graduating class of 1948. Special entertainment is being planned; there will be no speeches.

IOWA

State Medical Meeting.—The Iowa State Medical Society will hold its ninety-seventh annual session at the Hotel Fort Des Moines, Des Moines, April 18-21 under the presidency of Dr. Harold A. Spilman, Ottumwa. Twelve guest speakers will give papers at the general sessions:

Howard B. Burchell, Rochester, Minn., Diagnosis of Congenital Heart Disease with Respect to Cardiac Catheterization and Oximetry.
John H. Moe, Minneapolis, Fractures of Neck of Femur.
Winthrop M. Phelps, Baltimore, Cerebral Palsy.
Charles D. May, Minneapolis, Chronic Disorders of the Digestive System in Children.
Walter C. Alvarez, Rochester, Minn., What Can the General Practitioner Do for the Nervous Patient?
W. Walter Wasson, Denver, The Lesser Circulation.
James S. Speed, Memphis, Tenn., Ruptured Intervertebral Disks.
Alson E. Braley, New York, Relation Between Ocular Disorders and Thyroid Dysfunction.
Willis J. Potts, Chicago, Diagnosis and Surgical Treatment of Patent Ductus Arteriosus and Congenital Vascular Ring.
Elmer L. Henderson, Louisville, Chairman, Board of Trustees, American Medical Association, World Medical Association.
M. Edward Davis, Chicago, Modern Management of Third Stage and Postpartum Hemorrhage.
Roland S. Cron, Milwaukee, Wis., Treatment of Carcinoma of the Cervix.

The annual banquet will be April 20 at 7 p.m. The Woman's Auxiliary to the society will meet April 19 and 20 at the Hotel Savery, and special luncheons and dinners have been scheduled for a number of state societies.

KANSAS

The Porter Lectures.—Dr. Chester S Keefer Boston; delivered the Porter Lectures March 39-31 at the University of Kansas School of Medicine Lawrence and Kansas City. His subjects were " Penicillin in the Medical and Surgical Practice," "Antibacterial Agents from Microbes" and " Streptomycin in the treatment of infections

Appoint Professor of Pathology. — Dr. Robert E. Stowell, formerly assistant professor of pathology at Washington University School of Medicine, St. Louis, has been appointed professor of pathology and oncology at the University of Kansas School of Medicine, Lawrence-Kansas City, effective March 1. Dr. Stowell received his M.D. degree from Stanford University School of Medicine, San Francisco, in 1941 and his Ph.D. degree from Washington University School of Medicine, where he has been on the staff since 1940.

MASSACHUSETTS

Nye Memorial Study.—The Massachusetts Division of the American Cancer Society, Inc. has granted Massachusetts General Hospital about $2,500, donated in memory of the late Dr. Robert N. Nye. The sum will be used to initiate and at least partly support the Robert Nason Nye Memorial Study. This study, a long-desired project of the x-ray department of the hospital where Dr. Nye served his internship, is concerned with the evaluation of changes in the peripheral blood correlated with known amounts of exposure to radiation sustained by the employees and staff of the x-ray department. Among other subjects to be studied is the incidence of leukemia among workers.

NEW YORK

Buffalo Alumni Clinical Day—The annual Clinical Day of the Alumni Association of the university of Buffalo School of Medicine, Buffalo, will be held April 17 at the Hotel Statler, Buffalo. Subjects under discussion include massive hemorrhage from peptic ulcer, management of gynecologic conditions, early recognition of pulmonary disease and diagnosis of respiratory symtoms in infancy. Class reunions will be held April 16 for the classes of 1883, 1888, 1892, 1898, 1903, 1908, 1913, 1923, 1928, 1933, 1938, and 1943.

New York City

Residencies Available.—The psychiatric division of the Kings County Hospital, Brooklyn, has a number of residents' positions available for appointment. This new psychiatric hospital is affiliated with the Long Island College of Medicine. Opportunities are available for degrees in graduate work during the residency. The standard resident's salary is $1,560 with maintenance. For information address the director of psychiatry, Dr. Sam Parker, Kings County Hospital, Albany Avenue and Winthrop Street, Brooklyn 3.

PENNSYLVANIA

Personal. — Dr. Charles C. Collester, Spencer, has retired from medical practice after thirty-five years of service to his community.

Society News.—At a meeting of the Reading Eye, Ear, Nose and Throat Society and the Diplomates Association of Berks County Physicians, Dr. Leandro M. Tocantins, Philadelphia, spoke on "The Critical Appraisal of Available Methods for the Control of Hemorrhagic States.

Philadelphia

Phi Lambda Kappa Lecture.—Dr. Lester R. Dragstedt Chicago, will deliver the second annual Phi Lambda Kappa Fraternity Lecture April 14 at 8:30 p.m in the Klahr Auditorium of thr Hahnemann Medical College on 'Vatogomy in the treatment of Peptic Ulcer."

Dr. Long Receives Honorary Degree. — Dr. Esmond R. Long, director; Henry Phipps Institute for the Study, Treatment and Prevention of Tuberculosis, University of Pennsylvania, received the honorary degree of doctor of science at a convocation in the various medical divisions of the university, March 6. Dr. Long has just returned from Germany, where he served on an Army commission for the study of tuberculosis in the American zone.

TENNESSEE

Annual Meeting of State Association.—The Tennessee State Medical Association will hold its annual meeting at the Maxwell House, Nashville, April 13-15 under the presidency of Dr. Franklin B. Bogart, Chattanooga. The tentative program lists the following guest speakers:

Axel N. Arneson, St. Louis, Prognosis in Carcinoma of the Uterine Cervix.
Byrl R. Kirklin, Rochester, Minn.Diaphragmatic Hernia.
Charles F. McKhann, Cleveland, Chronic Malnutrition in Children.
John Caffey, New York, Congenital Obstruction of the Alimentary Tract.
Fred V. Hein, Ph.D., Chicago, Physical Education and Athletics as Related to School Health.

The banquet in honor of President Bogart will be given April 14. Mr. Mac F. Cahal, Chicago, will speak on " Caution! Curves Ahead." The Woman's Auxiliary will meet April 13-15 with headquarters at the Hermitage.

TEXAS

Lectures by Dr. Best.—Dr. Charles H. Best, Toronto, Canada, delivered the annual Phi Beta Pi Lecture at Baylor University College of Medicine, Houston, March 22 on "The Pancreas as the Guardian of the Liver"; on March 25 he delivered the Albert Surman Memorial Lecture under the auspices of Phi Beta Pi Medical Fraternity at the University of Texas Medical Branch, Galveston. He also gave a series of four lectures on the physiology of carbohydrate and fat metabolism at Baylor University during the week.

Conference Pediatric.—A Pediatric postgraduate conference will be held at the University of Texas School of Medicine, Galveston, April 12-17 under e auspices of the university's Child Health Program and in cooperation with the Maternal and Child Health Division of the Texas State Board of Health. The subjects of the program on Monday will be the problem of infantile diarrhea and heart disease; on Tuesday poliomyelitis, and physiology of the newborn; on Wednesday, speech and speech correction: on Thursday, infant feeding and infectious diseases (continued) and on Saturday papers will be presented on adenoid pathology, deafness and acute poisonings.

WEST VIRGINIA

Meeting on Industrial Medicine.—A meeting, of physicians and nurses engaged in industrial work, sponsored by the industrial committee of the Kanawha Medical Society, will be held at the Ruffner Hotel in Charleston April 11. Sessions will begin at 10:20 a.m. The program follows:

Ralph S. McLaughlin, Charleston, Chemical Injuries to the Eye.
E. Hunter Boggs, Charleston, Industrial Skin Lesions.
Theodore P. Mantz, Charleston, Methods of Skin Grafting.
Walter G. Putschar, Charleston, Dangers and Pitfalls in Intravenous Medication.
J. Huber Wagner, Pittsburgh, Present Treatment of Wounds.
Bert Bradford Jr., Charleston, Treatment of Abdominal Injuries.
Henry M. Escue, Charleston, W. Va., Treatment of Urinary Bladder and Urethral Trauma.
Dr. J. Huber Wagner, Pittsburgh, will meet with members of the college at noon to discuss organizational matters.

WISCONSIN

Cancer Symposium in Milwaukee.—The Medical Society of Milwaukee County and the Milwaukee Division of the American Cancer Society, Inc. will present their second annual Cancer Symposium April 8-9 in Milwaukee. A clinic will be held at the Milwaukee Cancer Detection Center, and an address will be given at Marquette University School of Medicine auditorium at 8 p.m. followed by a panel discussion on "Management of the Late Cancer Patient". After the clinic group meeting at the Milwaukee County Hospital April 9 the following program, to be given at 2 p.m., has been arranged:

Arthur C. Allen, New York, Practical Fundamentals of the Nevi and Melanoma Problems.
J. Barrett Brown, St. Louis, Cancer of the Lip and Mouth.
Leon Schiff, Cincinnati, When Does Jaundice Mean Cancer?
Vernon C. David, Chicago, Indications for Surgical Procedures in Cancer of Rectum.

At 2 p.m. April 10 Dr. Allen will conduct a slide seminar on dermatologic lesions. All interested physicians are invited to attend.

GENERAL

Annual Specialists' Meeting.—The American Laryngological, Rhinological and Otological Society, Inc. will hold its annual meeting April 7-9 at Chalfonte-Haddon Hall, Atlantic City, N. J., under the presidency of Dr. Lyman G. Richards, Brookline, Mass. Physicians invited to take part in discussions include Arthur M. Olsen, Rochester, Minn.; Hallowell Davis, St. Louis; Stuart C. Cullen, Iowa City, and Morris Fishbein, Chicago.

Students International Clinical Congress.—The International Union of Students and the British Medical Students Association invites a delegation of fifteen medical students from the United States to a Students' International Clinical Congress of two hundred delegates in England July 6-24, 1948. Lectures and clinical teaching will be held in London, Oxford and Birmingham. Transportation and housing will be arranged at minimal expense. For information write Anna P. Cort, Chairman, Committee on International Teaching Congress, AIMS, Boston University School of Medicine, 80 East Concord Street, Boston.

Southeastern Surgical Congress.—The sixteenth annual postgraduate assembly of the Southeastern Surgical Congress will be held in Hollywood, Fla., April 5-8 at the Hollywood Beach Hotel, under the presidency of Dr. Herbert Acuff. The papers to be presented are intended to make up an inclusive refresher course. The C. Jeff Miller Lectureship will be presented Monday, 8 p.m., by Dr. R. L. Sanders, University of Tennessee College of Medicine, Memphis, on "Palliative Treatment for Carcinoma of the Pancreas." The Southeastern Surgical Congress recently purchased the old John P. Huntley home, 1439 Peachtree Street, Atlanta, Ga., as general headquarters for the congress.

Meeting of Laryngological Association.—The annual meeting of the American Laryngological Association will be held at the Homestead, Hot Springs, Va., April 14-15 under the presidency of Dr. Arthur W. Proetz, St. Louis Physicians presenting papers by invitation are:

Harold I. Lillie and Clifford F. Lake, Rochester, Minn., Mucoceles, Pyoceles and Cystic Degenerative Lesions of the Mucous Membrane of the Frontal and Ethmoidal Paranasal Sinuses.
Ko K. Chen, Indianapolis, Aliphatic Versus Aromatic Amines as Vasoconstrictors.
Edwin N. Broyles and Edward M. Walzl, Baltimore, Postoperative Course of Subperichondral Total Laryngectomies.

The president's reception at 6 p.m. April 14 will be followed by the annual banquet for fellows only.

MARRIAGES

JOHN KINGSLEY LATTIMER to Miss Jamie Elizabeth Hill, both of Jackson Heights, N.Y., January 23.

HERMAN N. EISEN, Brooklyn, to NATALIE ARONSON of New York, in February.

HARRISON CLINTON FLOURNOY, Warwick, Ga., to Miss Altalene Ethel Russell of Eufaula, Ala., in Shellman, Ga., February 2.

CRAIG WILLIAMSON, Upland, Calif., to Miss Betty Lucile Payne of Los Angeles.

JAMES SAMUEL GARNER Jr., Plant City, Fla., to Miss Mary Elizabeth Arnold of Washington, D.C., at Falls Church, Va., February.

JOHN JOSEPH McGILLICUDDY, Lynn Mass., to Miss Mary Louise Godvin of Orange, N.J., at Chestnut Hill, Mass., recently.

GEORGE LEGARE KERRISON to Miss Mildred Virginia Burdashaw, both of Charleston, S.C.; February 10.

Deaths

Gilbert Seymour Osincup ⊕ Orlando, Fla.; born in Cedar Rapids, Iowa, Jan. 17, 1894; University of Tennessee College of Medicine, Memphis, 1916; past president of the Florida Medical Association and of the Orange County Medical Society; fellow of the American Academy of Pediatrics; specialist certified by the American Board of Pediatrics; served with a British infantry regiment and the Royal Air Force during World War I and was decorated by King George V of England with the British Military Cross; in 1946 retired as senior surgeon, U. S. Public Health Service reserve, and during World War II served in the European and Middle Eastern theaters of operation, assigned to British Occupational Forces in Greece; formerly served on the Florida Defense Council as chairman of health and housing and as chairman of selective service for Orange County; received the certificate of honor from the Florida Medical Association and the Selective Service Medal from President Truman; served as president of the medical staff of Orange Memorial Hospital, where he had been chief of the pediatric service for many years; died Nov. 26, 1947, aged 52, of carcinoma of the lungs.

Fred Towsley Murphy, Grosse Pointe, Mich.; born in Detroit Oct. 23, 1872; Harvard Medical School, Boston, 1901; at one time on the faculty of his alma mater and professor of surgery at the Washington University School of Medicine in St. Louis; member of the American Medical Association, serving as a delegate from Massachusetts in 1911; member of the Massachusetts Medical Society, American Surgical Association and the Society of Clinical Surgery; fellow of the American College of Surgeons; member of the founders group of the American Board of Surgery; during World War I a commanding officer of Base Hospital 21 in France; awarded the Distinguished Service Medal for supervising evacuation of First Army casualties, and later became director of medicine and surgery for the American Red Cross; in 1921 became a brigadier general in the U.S. Army reserve; at one time on the staffs of the Infants' Hospital in Boston and the Barnes Hospital in St. Louis; member of the board at Harper Hospital in Detroit; a trustee of Phillips Andover Academy in Andover, Mass.; died January 10, aged 75, of bronchopneumonia.

Archibald Alexander MacLachlan ⊕ Pittsburgh; born in Claysville, Pa.; in 1874; University of Pennsylvania Department of Medicine, Philadelphia, 1900; served on the faculty of the University of Pittsburgh School of Medicine; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology and of the American Laryngological, Rhinological and Otological Society; fellow of the American College of Surgeons; affiliated with the Eye and Ear and Southside hospitals; died at his home in Library, Pa., Dec. 2, 1947, aged 73.

Joseph Moses Jr., Northfield, Minn.; born in Herman, Minn. Nov. 17, 1887; University of Minnesota Medical School, Minneapolis, 1914; member of the American Medical Association; past president of the Rice County Medical Society; served during World War I; chairman of the Rice County Public Health Association, and during World War II served as medical examiner for war services; member of the board of education; vice president of the Northfield National Bank; died recently, aged 60, of coronary thrombosis.

Charles Fisher Lippe, New York; New York University College of Medicine, 1939; diplomate of the National Board of Medical Examiners; served as a lieutenant commander in the medical corps of the U. S. Naval Reserve during World War II; resident at Veterans Administration Hospital in Fort Logan, Colo.; interned at the Hospital for Joint Diseases in New York; formerly resident at Sea View Hospital in Staten Island and Mount Sinai Hospital in New York; died recently, aged 33, of coronary disease.

George Everet Alexander, Castle Rock, Colo.; University of Buffalo School of Medicine, 1885; member of the American Medical Association; served as county health officer; died recently, aged 88.

Joseph Long Alexander, Staunton, Va.; University of Virginia Department of Medicine, Charlottesville, 1900; member of the American Medical Association; affiliated with the Kings' Daughters' Hospital, where he died Dec. 16, 1947, aged 70, of chronic myocarditis.

Clayton Witters Bartlett, Bennington, Vt.; University of Vermont College of Medicine, Burlington, 1888; member of the American Medical Association; fellow of the American College of Surgeons; died Dec. 23, 1947, aged 82, of arteriosclerotic heart disease.

William Alonzo Bockoven ⊕ Cresco, Iowa; State University of Iowa College of Medicine, Iowa City, 1921; fellow of the American College of Surgeons; member of the school board; affiliated with Decorah Hospital in Decorah and St. Joseph Mercy Hospital; died Dec. 30, 1947, aged 53, of coronary thrombosis.

James Marshall Braden, Lafayette, Colo.; Hospital College of Medicine, Louisville, Ky., 1891; at one time health officer of Carbondale; served during World War I; twice mayor of Lafayette; died in the Community Hospital, Boulder, Nov. 29, 1947, aged 79.

Edgar Marx Braun, Irvington, N. J.; Duke University School of Medicine, Durham, N.C., 1936; member of the American Medical Association; diplomate of the National Board of Medical Examiners; died in East Orange Dec. 26, 1947, aged 38, of coronary occlusion.

William O. Burbank, Gaines, N.Y.; University of Buffalo School of Medicine, 1889; formerly a member of the school board, health officer and coroner of Pavilion; died in St. Jerome Hospital, Batavia, Dec. 24, 1947, aged 87, of arteriosclerosis and bronchopneumonia.

William Alvin Camp ⊕ Cullman, Ala.; Emory University School of Medicine, Atlanta, 1941; interned at the Employees' Hospital of the Tennessee Coal, Iron and Railroad Company in Fairfield; served during World War II; affiliated with the Cullman Hospital; died Nov. 29, 1947, aged 32, of coronary thrombosis.

Benjamin L. Carter, Covington, Va.; Baltimore Medical College, 1893; member of the American Medical Association; served as secretary of the Alleghany County Board of Health; chairman of the board of directors of the Citizens National Bank; died Dec. 7, 1947, aged 82, of coronary thrombosis.

Andrew Jackson Cooper, Midland, Texas (licensed in Texas under the Act of 1907); member of the American Medical Association; during World War I on the examining board of Taylor County, where he had been county health officer; at one time served as local surgeon for the Missouri, Kansas and Texas and the Frisco railroads; died Dec. 24, 1947, aged 72, of cardiovascular disease.

Noah Albert Davidson, Harlingen, Texas; Baylor University College of Medicine, Dallas, 1911; member of the American Medical Association; died Dec. 10, 1947, aged 66.

Roy Edgar Emanuel ⊕ Chickasha, Okla.; University of Oklahoma School of Medicine, Oklahoma City, 1926; served as vice president of the Oklahoma State Medical Association; affiliated with the General Hospital; died Dec. 6, 1947, aged 46, in an airplane accident.

Jack Albert Churchill King, Vevay, Ind.; University of Michigan Medical School, Ann Arbor, 1933; member of the American Medical Association; past president of the Switzerland County Medical Society; died Dec. 6, 1947, aged 41.

John Elwood Knight ⊕ Warrenton, Va.; Medical College of Virginia, Richmond, 1908; formerly vice president of the Medical Society of Virginia; served as vice president of the Fauquier County Medical Society; died Dec. 30, 1947, aged 64, of heart disease.

Arthur Dillard Harmon Little, Thomasville, Ga.; Medical Departmentof Tulane University of Louisiana, New Orleans, 1908; member of the American Medical Association and of the Southeastern Surgical Congress; fellow of the American College of Surgeons; for many years a member of the board of education; served during World War I; affiliated with the Archbold Memorial Hospital, where he died recently, aged 66, of coronary thrombosis.

Clarence Homer Lefever, Erie, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1902; member of the American Medical Association; past secretary and president of the Erie County Medical Society; chief of medical service at St. Vincent's Hospital, where he died January 11, aged 73, of a fracture of the vertebrae and subacute lateral sclerosis.

Benjamin Meyer Levine, Forest Hills, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1906; member of the American Medical Association; died recently, aged 62, of coronary disease.

Daniel W. Lowe, Woodsfield, Ohio; Starling Medical College, Columbus, 1903; member of the American Medical Association; formerly county health commissioner; died Dec. 2, 1947, aged 72, of heart disease.

Joseph Luff, Independence, Mo.; Kansas City (Mo.) Hahnemann Medical College, 1903; also a minister; died January 6, aged 95.

Bernard Norton MacLafferty, Malone, Wash.; American Medical Missionary College, Battle Creek, Mich., and Chicago, 1904; died Dec. 8, 1947, aged 69, of coronary thrombosis.

John Archibald MacMillan, Brookline, Mass.; Hahnemann Medical College and Hospital of Philadelphia, 1906; formerly assistant professor of clinical dermatology at the Boston University School of Medicine; member of the New England Dermatological Society; died Dec. 19, 1947, aged 64, of cerebral hemorrhage.

Fred Wasco Maxey, Superior, Neb.; Central Medical College of St. Joseph, Mo., 1905; veteran of the Spanish-American War; died Dec. 7, 1947, aged 71.

Charles C. Meade, Cincinnati; Pulte Medical College, Homeopathic, Cincinnati, 1890; died recently, aged 85.

Clarence Beacom Millhoff ⊕ Johnstown, Pa.; Jefferson Medical College of Philadelphia, 1897; died recently, aged 74.

George A. Morley, Crookston, Minn.; Rush Medical College, Chicago, 1897; past president of the public school system; member of the American Medical Association and of the American Academy of Ophthalmology and Otolaryngology; specialist certified by American Board of Ophthalmology; affiliated with Bethesda and St. Vincent's hospitals; died recently, aged 79, of heart disease.

Ernst H. Schoen, Jackson, Mo.; Homeopathic Medical College of Missouri, St. Louis, 1895; member of the American Medical Association; died Nov. 23, 1947, aged 74, of cerebral hemorrhage.

Christian Ulrich Senn ⊕ Ripon, Wis.; Wisconsin College of Physicians and Surgeons, Milwaukee, 1906; served during World War I; examining physician for the Selective Service Board during World War II; affiliated with Ripon Municipal Hospital, where he died Nov. 28, 1947, aged 69, of cerebral hemorrhage.

Walter Lewis Tanner, Newark, N. J.; Boston University Medical School, 1919; found dead in Philadelphia Dec. 16, 1947, aged 54.

Ralph Waldo Thompson Cornwall-on-the Hudson, N.Y.; New York Homeopathic Medical College and Flower Hospital in New York, 1908; health officer; died January 12, aged 71, of carcinoma.

Charles Burleigh Thomas, Cleveland; Cleveland Medical College, Homeopathic, 1891; served in France during World War I; died in East Cleveland Dec. 30, 1847, aged 81.

James Edward Trotman, Oklahoma City, Okla.; Meharry Medical College, Nashville, Tenn., 1936; died in the Massachusetts Memorial Hospital, Boston, Dec. 17, 1947, aged 49, of rapidly progressive hypertension.

William Miles Wallis Maryville, Mo.; Central Medical College of St. Joseph, Mo., 1903; served during World War I; affiliated with St. Francis Hospital; died Dec. 12, 1947, aged 67, of myocarditis.

Albert Davis Webb, Williamstown, Ky.; Medical College of Ohio, Cincinnati, 1886; also a druggist; died Dec. 19, 1947, aged 85, of pneumonia.

Hyman Wechsler, Los Angeles; Medical College of Indiana, Indianapolis, 1883; died recently, aged 90.

Edgemont David Welsh, Grand Rapids, Mich.; Michigan College of Medicine and Surgery, Detroit, 1905; died Dec. 5, 1947, aged 63, of coronary thrombosis.

Edward Augustus Williamson, Stamford, Conn.; Bellevue Hospital Medical College, New York, 1886; served during World War I; member of the staff of Stamford Hospital, where he died January 6, aged 83, of a fractured hip and hypostatic pneumonia.

Thomas Valentine Williamson, Norfolk, Va.; University of Virginia Department of Medicine, Charlottesville, 1908; served during World War I; affiliated with the Norfolk General and Leigh Memorial hospitals; died Dec. 29, 1947, aged 63, of heart disease.

Leon Gilbert Woodford ⊕ Everett, Wash.; Denver and Gross College of Medicine, 1909; fellow of the American College of Chest Physicians; formerly city physician; chairman of the advisory board of the Salvation Army; affiliated with Everett General Hospital and Providence Hospital, where he died Dec. 28, 1947, aged 65, of hypertension and cardiovascular renal disease.

Public Health in France Since the Liberation

In a press conference of January 15, Dr. Cavaillongeneral director to the Ministry for Public Health and Population, emphasized that, though being less serious than in 1943 and 1944, the situation with regard to public health has not improved greatly since 1946. Health examinations of school children and adolescents show many deficiencies resulting from undernourishment due to food shortages

Epidemic Diseases Under Control

Since 1945, there have been only 395 cases of exanthematous typhus, all but four or five in prisoners or deportees returning from Germany. A small outbreak of plague (13 cases) was rapidly checked by vaccination of the inhabitants of Ajaccio. Scarlet fever was reduced from 30,000 cases in 1946 to 4,000 in 1947, and measles from 30,000 in 1946 to 16,000 in 1947. Diphtheria was increased from 17,000 cases in 1938 to 45,000 in 1945, and then reduced to 9,700 in 1947. Poliomyelitis was reduced to 1,148 cases in 1947 and 46 cases of smallpox occurred. No case of cholera was imported to France from epidemic areas in Asia. Syphilis is also showing notable decrease.

Tuberculosis

In 1947 figures for tuberculosis were the lowest ever recorded, 89 cases per hundred thousand inhabitants. Numerous deaths during the occupation reduced the global number of patients with active infection: nevertheless, there is a decrease due to early detection, isolation of the patient and treatment. Tuberculosis is still serious because of underfeeding in cities, the difficulty of obtaining sufficient food in sanatoriums and the present impossibility of expanding sanatorium facilities.

Infant Mortality

Infant mortality increased during the war and the occupation, reaching a maximum in 1945 with a rate of 10.8 per cent. Regression is noted for 1947 (6.5 per cent). This rate is still high compared with that of other countries, as nearly 100,000 children under 1 year of age die every year in France. Results are due to a large number of medical and sanitary conditions, most of which can be corrected. Improvement is expected in the coming year.,

General Mortality

The prewar mortality rate in France was 1.57 per cent; it rose to 2.04 in 1944 and dropped to 1.34 in 1947. France as a whole requires continued improvement of health measures and war increased the need for better sanitary facilities and equipment. Thirteen new hospitals are now under construction and others, which were in course of construction before the war, will soon be finished.

Death of Philippo Pagniez

Philippe Pagniez died at the age of 74. As a Member of the National Academy of Medicine, he took part in the scientific direction of *La presse medicale*. Dr. Pagniez's main work, in the field of neurology, is epilepsy; in his famous book on that subject he brought to the fore the two factors, one nervous, the other humoral, which intervene in the pathologic processes of this disease. By patient research and observation he demonstrated the modification in the composition of the blood in epileptic persons, modifications brought about by a hemoclastic crisis-anaphylactic shock, which can set off authentic convulsive paroxysms. He discovered the essential cause of the guinea pig's epilepsy, described by Brown-Sequard. Pagniez is well known for his hematologic work, including that on hemolysins and agglutinins. His work in the fields of allergy and anaphylaxis has contributed greatly to the solution of the problem of allergy of the digestive tract. With Pasteur Vallery-Radot, he has shown the part played by the humoral imbalance in the genesis of migraine.

Miscellaneous

Professor B. Houssay, of Buenos Ayres, Doctor Honoris Causa of the Paris University, Nobel prize winner, delivered a lecture at the Paris Faculty of Medicine on experimental diabetes. Professor E. Cruz-Coke of Santiago, recently made Doctor Honoris Causa of the Paris University, delivered a lecture on arterial hypertension of renal origin at the Paris Faculty of Medicine.

The Medical Days of the Propedeutic Clinics of the Broussais Hospital will take place in Paris, May 21-23 under Professor Pasteur Vallery-Radot. For information apply to Professor J. Hamburger, 29 Boulevard de Courcelles, Paris.

The First International Congress on Surgical Films, organized by "Art and Science", took place in Paris, April 7, 1948, at "Mutualite" Palace.

Biliary Radiomanometry

At the Belgian Society of Gastroenterology, Caroli of Paris presented his six years' experience with radiomanometry, which combines the technics to measure the pressure necessary for the perfusion of the biliary passages when drains have been placed after surgical intervention and those which are used for contrast mediums that are introduced for the radiographic study of the biliary passages.

The author employs "tenebryl" (aiodine (preparation) as a contrast medium. The zero point of the manometer is placed on the level of the choledochoduodenal juncture. He visualizes the introduction of the contrast liquid in the gallbladder, measures the pressure of filling of the latter and takes a picture Then he measures the pressure necessary to pass the sphincter of the gallbladder; this pressure varies between 12 and 14 cm. of water.

In the normal subject, as soon as the sphincter of the gallbladder is passed, the biliary tree is filled without stoppage up to the duodenum. When the biliary tree is thus filled, it is advisable to take serial pictures. One sees then the movements of closing and opening of the sphincter of Oddi, giving rise to veritable ejaculations of contrast liquid into the duodenum. The pressure required to pass this choledochoduodenal juncture is between 10 and 12 cm. of water, that is to say, lower than that required for the passage of the vesical sphincter. If it is necessary to reach a pressure of 20 cm. of water and more, it is an indication of an organic lesion and if instead of employing surgical treatment only a cholecystectomy is made, the latter will be followed by pain.

Correspondence

MALIGNANT EXOPHTALMOS

To the Editor:—In view of the general air of pessimism which permeates the approach to malignant exophthalmos, an attitude shared by your contributor Dr. Willard O. Thompson (THE JOURNAL, January 31, p. 314) in his recent delightful article, perhaps it is worth while briefly to record 2 cases of successful treatment.

The first patient was a Royal Air Force flight sergeant pilot aged 28, who eight years before had had an operation for a large simple goiter. He was referred for increase in weight, shortness of breath, lethargy, slowing of thought and moderate exophthalmos. He presented classic features of early myxedema: a skiagram of the chest showed tracheal compression from a substernal goiter: the goitrous mass was resected and thyroid sicca (B.P.) ½ grain (0.03 Gm.) three times a day and Lugol's solution 5 minims (0.31 cc.) three times a day were prescribed. His general condition improved immensely: the exophthalmos receded rapidly, and within three months of his first being seen he was considered fit enough to return to operational flying duty. Unfortunately, the exigencies of the service prevented full follow-up, but when last seen he was well and symptom free, taking 1½ grains (0.10 Gm.) of thyroid sicca daily.

The second patient was a girl aged 19 who was referred with a presumptive diagnosis of exophthalmic goiter. She had suffered from bronchial asthma since childhood and had always been of nervous disposition. There was moderate exophthalmos: the thyroid was diffusely enlarged to about thrice its normal size, and there were pronounced tremors of the extended fingers. She had, however, recently gained weight and the hands, even on a warm day, were abnormally cold. Psychologic history revealed personality inadequacy with fairly severe emotional conflicts and features of chronic anxiety. Accordingly the diagnosis was "chronic anxiety state with hypothyroidism and thyrotropic exophthalmos". She was admitted to hospital and given thyroid sicca 5 grains (0.32 Gm.) three times a day and Lugol's iodine 5 minims (0.31 cc.) three times a day. Within a week the exophthalmos had noticeably diminished and the thyroid had reverted almost to its normal size and consistency. Shortly afterward, she was discharged to outpatient care and seen at regular intervals, continuing to take 1 grain (0.06 Gm.) of dried thyroid daily. A year after her first being seen the eyes were only slightly prominent, and no abnormality of the thyroid was palpable. Further, her asthmatic attacks were much diminished in severity and frequency. Her dose of thyroid sicca had now been reduced to ½ grain (0.03 Gm.) daily and the iodine had been omitted.

Both of these patients were seen within a few days of their first noticing the prominence of the eyes, and in both treatment was begun early. This may account for the good results obtained and should encourage one to bear this possible diagnosis in mind when seeing cases which at first sight suggest Graves' disease, diffuse goiter with hyperthyroidism. The second patient had already been seen by several physicians who had accepted the diagnosis of primary thyrotoxicosis. It is probable that, if corresponding lines of treatment had been followed, the ultimate results would not have been so good. As it was, the final outcome in both instances should perhaps encourage us to discard the rather terrifying name which has been attached to this condition.

J. DONALDSON CRAIG, M.D.
72 Westbourne Terrace,
London W. 2, England.

NOTE ON THE INCEPTION OF THE ASSOCIATION OF AMERICAN MEDICAL COLLEGES

To the Editor:—In 1890 while studying abroad I received letters from my father, Dr. Aaron Friedenwald, professor of ophthalmology in the College of Physicians and Surgeons of Baltimore. The following excerpts throw an interesting light on the creation of the Association of American Medical Colleges.

Excerpt from letter dated Jan. 30, 1890:

> Dr. Cordell has stirred up the profession in Baltimore in reference to the Colleges' raising their standard. The University of Maryland a few weeks ago announced that from the next session a compulsory three year graded course would be adopted. Dr. Latimer and I were appointed a committee to represent the College of Physicians and Surgeons at a meeting (of the faculty) held last week. I took the ground that the simple adoption of a three years' course by the colleges of this city might not accomplish at all what the profession seemed so much to desire. I could imagine a result which would attract the students, who would be prevented by such an action to come to Baltimore, to colleges whose requirements were not so high. In such a case, the profession at large would not be benefited, but very probably the college might be made to suffer to an extent that would greatly endanger its existence. I therefore preferred that a circular should be sent to all colleges of the United States having a two years' course (asking them) to send delegates to the meeting to take place in Nashville (Tenn.) in May next, when the American Medical Association will meet there, for the organization of an Association of American Medical Colleges, whose purpose it shall be to elevate the standard by a concert of action; the delegates sent to this meeting to be instructed to vote for a three year graded course. I think the time an opportune one to bring about this result. It is true that a similar effort ended in failure about twelve years ago. The *vis a tergo* in the shape of the state medical examinations, which so many states have adopted, did not exist at that time, and it seems to me the best way out of the difficulty. My proposition met with favor, and tomorrow there will be another meeting to consider the circular, the preparation of which has been entrusted to Dr. Cordell. If this effort will be successful, it will be a great achievement, and our college will have the credit of first proposing a practical method of disposing of this vexed question.

Excerpt from letter dated Feb. 9, 1890:

> On last Thursday a meeting of the representatives of the various medical colleges in Baltimore took place and my proposition to send a circular to all medical colleges in the United States for a meeting in Nashville in May, to raise the standard of medical education by a concerted movement, was adopted. I hope that this will lead to something.

The call for the meeting went out over the signatures of A. Friedenwald, chairman, and E. F. Cordell, secretary. The former was elected vice chairman of the newly formed association.

HARRY FRIEDENWALD, M.D., Baltimore.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Food and Drug Acts: Evidence of Misbranding of Device.—The United States filed a libel against sixteen Sinuothermic machines, owned or manufactured by the claimant, on the ground that they were misbranded when shipped in interstate commerce. The misbranding was alleged to have consisted of printed matter accompanying them which represented that the machines had a therapeutic value in the diagnosis and treatment of stated diseases of man, whereas the devices were not effective for such purposes. From a judgment of condemnation and destruction, the claimant appealed to the circuit court of appeals, fifth circuit.

The federal law prohibits the introduction into and the receipt in interstate commerce of any food, drug, device or cosmetic that is adulterated or misbranded and provides for seizure and condemnation of such. It is not denied that these machines were devices within the act. A drug or device shall be deemed to be misbranded, within the federal act, if its labeling is false or misleading in any particular. The term "labeling" means all labels and other written, printed or graphic matter on any article or any of its containers or wrappers or accompanying such article. The last three words, said the court of appeals, are critical here. They make the term "labeling" broader than "label," which includes only what is displayed on the immediate container of an article. How much broader? The sixteen devices in question were shipped in several consignments from a place in Florida to a designated place in Ohio. The first three shipments went forward and were received by the proper party and put to work in his medical practice several weeks before any leaflets were sent. They did not accompany any of the devices while they were in interstate commerce. The last of the shipments went forward three weeks after the leaflets and was not accompanied by them. Accompany, said the court, means to go along with. In a criminal and forfeiture statute the meaning cannot be stretched. Furthermore, it may be doubted, said the court, that the printed matter is in its nature a labeling for the machines. It looks like a small newspaper, entitled "The Road to Health, by Dr. Fred Urbeteit. Every subject pertaining to Health, Doctoring and Nursing is being taught at the College of Sinuothermic Institute, Inc., 307 West Euclid Ave., Tampa, Florida." To the left of this heading is a picture of Dr. Fred Urbeteit, president of Sinuothermic Institute, Inc., and to the right an attractive picture of the institute and its grounds. Fifteen columns of fine print are below, consisting of testimonials and case histories of patients who had been treated at the institute by Dr. Urbeteit, with unstinted praise of both. The Sinuothermic machine is mentioned and praised as an instrument of diagnosis and treatment, but there is no description or picture of the machine, no explanation of its operation and no suggestion that it is for sale. The whole thing, said the court of appeals, appears to be an advertisement for the institute and Dr. Urbeteit, rather than something to accompany machines. Whether we ought to hold it a labeling of these machines if shipped simultaneously with them, the court continued, may be doubted. But if it could be called labeling, it is not proved by the present skimpy evidence that it accompanied the machines or any one of them while they were in interstate commerce.

The claimant vigorously contended that all he had said in "The Road to Health" was true. He offered in his claim, since no employee of the United States and only a few practitioners whom he had instructed, had any actual knowledge of his machine, to conduct a series of tests of it in cooperation with practitioners of medicine, osteopathy, chiropractic and naturopathy approved by the court, preferably on persons previously treated by medical practitioners without success, they to be examined before and after the test by physicians appointed by the court during such period as the court should fix, the physicians' determination of the results to be evidence in the case. This was not done. Dr. Urbeteit at least seems convinced of the efficacy of his machine, said the court of appeals. He testified in detail as to each case mentioned in "The Road to Health." He had present 30 of his patients, whom he offered as witnesses to the benefits they had received, many of them being those mentioned in "The Road to Health." The trial judge refused to hear them on the ground that, being laymen, they could not testify as to what was the matter with them and consequently could not say what they were relieved from, and that the diagnoses testified to by Dr. Urbeteit could not be accepted because he rested them on the use of his machine which the government's witnesses, who were men of high standing in medicine and in the electrical arts, had testified could not do what Dr. Urbeteit claimed. These rulings, said the court of appeals, were error. One was based on the idea that Dr. Urbeteit had made his diagnoses solely on the indications of the machine. But his testimony as a whole was that he used all known methods of diagnosis, that the machine did not indicate any particular disease but only located the spot where the abnormal tissue was, and that it was then a matter of judgment as to what the disease was. He only claimed the machine to be an aid in diagnosing. The patients themselves, said the court, could certainly know whether their external symptoms abated and their pains ceased. Urbeteit, being a licensed doctor of some twenty years' practice, could express expert opinions. The judge might, continued the circuit court of appeals, after hearing all the evidence, prefer the expert opinions of the government witnesses to those of Dr. Urbeteit, even as against the facts to which he and his witnesses might swear, but the judge should have heard all the competent testimony before making up his mind. The most eminent physicians and scientists have in the past erred in their opinions, and opinions generally must yield to well proved contrary facts. The case, the court concluded, ought to have been more fully tried. Accordingly, the judgment in favor of the government was reversed and the cause was remanded for further proceedings.—*Urbeteit v. United States, 164 F. (2d) 245 (1947).*

Medical Motion Pictures

NEW MOTION PICTURE ADDED TO A.M.A. LIBRARY

Surgery in Chest Diseases. 16 mm., black and white, sound, 1,400 feet (one reel), showing time forty-five minutes. Prepared in 1945 for the British Ministry of Information, London, England. Produced by G. B. Instructional, Ltd., London. Procurable on loan from the American Medical Association, Committee on Medical Motion Pictures, 535 North Dearborn St., Chicago, 10.

This motion picture portrays the diagnostic, surgical and rehabilitation technics in a large hospital for diseases of the chest. In particular, it follows one patient through all these procedures from the time that a cancer of the lung is recognized on a routine roentgen examination of the chest until he returns to work on an occupation suited to his convalescent regimen. This patient was in the hospital many weeks longer than necessary. Much of this time could well have been spent at home; his rehabilitation could have been conducted in an outpatient clinic and in various normal activities as well as in rehabilitation hospitals and elaborate occupational therapy shops.

Throughout the film one is impressed with the excellent organization of the subject and with the thoroughness and efficiency of the surgical management. The photography is excellent. This production would be suitable to those interested in the organization of public medical facilities. It would be of value to the general practitioner as a demonstration of the present status of surgical management of formidable thoracic conditions and also to the specialist in thoracic surgery as a demonstration of the particular technics in this clinic.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

Effect of Visual Training on Existing Myopia. H. R. Hildreth, W. H. Meinberg, B. Milder and others.—p. 1563.

Capillary Fragility and Retinal Hemorrhage.—Shanno nd his co-workers think that there is at least a possibility hat certain cases of retinal hemorrhage may be due to an lteration in the capillary wall which may be present throughout he body, although obvious lesions may appear only in the etina. To explore this possibility the authors have carried ut tests to demonstrate increase in capillary fragility and ermeability in the cutaneous capillaries, in patients with retinal emorrhage. Studies were made on 2 groups of patients, one consisting of 47 subjects with recent retinal hemorrhage who were referred from other dispensaries to a special one set up for this study. The second group consisted of 32 patients with retinal hemorrhage referred as private patients to one of the authors. It was found that a considerable number of patients with retinal hemorrhage have an associated generalized capillary abnormality, *as shown by abnormal response to tests* for capillary fragility and permeability carried out on the vessels of the skin. The recurrence of retinal hemorrhage during the period of study was usually but not invariably associated with either increased capillary fragility or permeability, as shown by the tests. Rutin therapy was followed by return of capillary fragility and permeability to normal in about half of the dispensary group and in about 70 per cent of the private group; in such subjects further retinal hemorrhage usually failed to develop. In view of the number of cases, the period of follow-up and the diversity of results final conclusions cannot be drawn, but it is at least suggestive that rutin administered in adequate dosage and over a sufficiently long period may be of value in preventing further retinal hemorrhage in that group of patients whose initial hemorrhage was associated with a generalized capillary fault.

Visual Training in Myopia.—Hildreth and others describe research undertaken in an effort to determine the value of visual training as a means of improving the visual acuity in patients with myopia. The procedure required an Arneson squint corrector, a Keystone "tel-eye trainer" with certain Keystone cards and an American Optical Company "Wells-head." The technic was broken into eleven individual steps laid out for a training period of twenty-four days averaging about one hour per day. Of 87 myopic patients 33 were either rejected or the training was incomplete, leaving 54 records for study. Thirty of the 54 patients showed no change in their acuity, while 12 showed a definite improvement, the best results being obtained in the patients with small degrees of myopia. Twelve patients showed a change so slight as to be excluded in the results. The change in the improved group averaged 27 per cent. Eleven of the 12 improved patients were rechecked at an interval of fifteen to twenty-three months after completion of training. Five of these retained their improvement, while only 1 had less than pretraining acuity. There was neither change in the refractive error nor significant alteration in the ocular neuromuscular mechanism. It was thought that the improvement probably occurred because of an improved reception due to stimulation of the visual effort. The authors conclude that visual training has a definite but limited value in some myopic patients. The effectiveness of visual training must be increased if it is to be generally applicable. Visual training merits further study by the ophthalmologist.

Streptomycin in Pulmonary Tuberculosis.—Barnwell and others of the Veterans Administration treated 223 patients with moderately and far advanced pulmonary tuberculosis with streptomycin by a uniform regimen in seven Army, Navy and Veterans Administration hospitals. The results of this cooperative venture are described *in summary form.* Seven additional reports describe in greater detail observations on groups of these patients. The roentgenographic changes in more than half of the cases were viewed by a *jury of phthisiologists* appointed by the American Trudeau Society. It was the judgment of the jury that little or no change occurred in the productive or fibrocaseous lesions during the hundred and twenty days of treatment but that some degree of clearing occurred in 85 per cent of unstable, exudative lesions, which had been unchanged or progressive in more than two-thirds of the cases for at least sixty days prior to streptomycin therapy. The judgment of the investigators supported that of the jury. This change in the trend of the disease is regarded as evidence that streptomycin can favorably affect pulmonary lesions of this character and that it is superior in this respect to the effects of rest in bed. Extension of lesions occurred in 8 per cent of cases toward the end of treatment in the present series and in 16 per cent during the first to fourth months following its completion. Conversion of results of sputum tests to negative occurred in 40 per cent. In the opinion of the investigators the role of *streptomycin in the treatment of pulmonary tuberculosis* lies in the partial clearing of exudative lesions, either as an end in itself or as a preliminary to the collapse measures which it often makes possible. *The clinical changes during streptomycin* therapy were as frequent as the roentgenographic changes and were more impressive in extent. Cough and sputum were *almost constantly reduced; fever, when it was present,* was similarly affected, and more than 80 per cent of the patients gained an average of 12 pounds (5.4 Kg.) in body weight.

Laboratory observations established or reaffirmed two gross disadvantages of streptomycin therapy: damage to the vestibular apparatus and the development of resistance by tubercle bacilli, which in all probability makes the long continuation of treatment unprofitable. The possibility of minimizing or avoiding these disadvantages by alterations of the regimen is being pursued.

Immunity to Diphtheria in Allergic Children.—Peshkin and Rapaport point out that detoxified crude bacterial filtrates and alum-precipitated toxoids are still mainly used in prophylaxis against diphtheria. As a consequence, disturbing systematic reactions occur, especially after the administration of a booster dose of toxoid to older children. Crude toxoid prepared by detoxification of bacterial filtrates with a 40 per cent solution of formaldehyde, in addition to proteins of true exotoxin contains somatic antigens, i. e., soluble substances of proteinic nature that form precipitins with antibacterial serum. Under controlled conditions selective absorption of somatic antigens with magnesium hydroxide can be achieved. This absorption, however, resulted in slight reduction of the total nitrogen content in the toxin. Later methods were developed which made it possible to eliminate more than 90 per cent of the original nitrogen. Purified toxoid was prepared from absorbed toxin by subsequent detoxification with formaldehyde, dialysis, absorption of the toxoid with calcium phosphate and, finally, elution of the purified toxoid. This method yields a highly purified product which contains little nitrogen, is free from bacillary proteins and remains highly antigenic. The authors used these purified diphtherial toxoids in 55 allergic children who had bronchial asthma, hay fever or both. Comparative intradermal tests with a 1:100 dilution of crude yellow diphtherial toxoid and eluted calcium phosphated toxoid showed the latter preparation to give a decidedly lower incidence of positive reactions. The eluted calcium phosphated diphtherial toxoid can be regarded as a preparation pointing to definite progress in the search for diphtherial toxoid capable of lowering the incidence of local, febrile or systemic allergic reactions following its use in allergic children.

Allergens of Mill Dust.—Jimenez-Diaz and his associates show that there exists in cereal dust different elements that can produce sensitization. In order of importance they are fungi, insects, acarina and substances in dust and flour itself. The fungi of greatest importance are rust, smut and Tilletia. They can be found in great quantities in granary dust and in that of milling establishments, owing to their fineness and the ease with which they spread once the covering of the invaded grain has broken. The infected grain, equally with Ustilago and Puccinia, can spread in the air at the time of seed falling, thus acting as causative agents in the sensitization of the population at large. Other fungi, such as Aspergillus and Penicillium, can invade damp flour, but this is a much rarer occurrence. Although little attention has been given to insects as causes of asthma, the authors mention observers who have described sensitization by trichoptera (Caddis fly), ephemerida, Musca domestica and Cimex lectularius. In farmers, in persons who live near granaries or in mill workers investigations carried out by the authors have shown that the sensitizing agent can be coleoptera. Sensitization to flour itself is of most importance among bakers.

Digitalis in Congestive Heart Failure.—LaDue and Carter report on 104 patients with heart disease associated with regular sinus rhythm who had been discharged from Charity Hospital after treatment for congestive heart failure and were followed in the clinic at intervals of from one to four weeks over a period of from six months to two years. At the time the study was begun most of the patients had been taking 0.1 to 0.3 Gm. of folia digitalis for several weeks or months after discharge from the hospital. The data obtained by the authors suggest that vital capacity, circulation time, venous pressure and weight are, at best, crude measurements of cardiac reserve and are less reliable in evaluating this important factor than a careful consideration of the symptoms and signs manifested by a patient with heart disease. This does not detract from the value of these measurements in the study or evaluation of the degree of congestive failure present and of the mechanisms involved in the production and disappearance of cardiac decompensation. Evidence of the efficacy of maintenance doses of folia digitalis in preventing the recurrence of congestive heart failure, although not clearcut, suggests that it may be desirable to keep patients who have had congestive heart failure on maintenance doses of folia digitalis, since the rate of recurrence is twice as great as when the drug is withheld.

Streptomycin in Pulmonary Tuberculosis.—Muschenheim and his associates discuss results observed in 43 patients with pulmonary tuberculosis who were treated with streptomycin for from forty-two to one hundred and twenty days. Of 18 patients whose pulmonary lesions were predominantly exudative, 9 attained satisfactory early remissions during or shortly after the cessation of therapy Of these, 2 relapsed within six months, requiring collapse therapy, and a third relapsed within twelve months. Another 6 patients showed considerable improvement under streptomycin therapy but fell short of attaining full remission. The suitability of these cases for collapse therapy, however, was appreciably enhanced, and this measure was subsequently undertaken in 5 with apparent success. In 3 patients there was no significant benefit and a short period of symptomatic improvement was followed by resumption of the progressive course. Of another 18 patients with chronic fibrocavernous disease, 4 had satisfactory early responses and 4 more attained favorable results when the antimicrobial therapy was followed by thoracoplasty. In 10 of the 18 cases there was a short period of temporary improvement but no lasting benefit. Strains of tubercle bacilli highly resistant to streptomycin in vitro were obtained from 10 of 11 patients who continued to discharge bacilli during seventy-five to one hundred and twenty days of chemotherapy. The incidence of drug-resistant strains of bacilli was much lower when streptomycin therapy was continued for only forty-two days. When relapse occurred after the appearance of streptomycin-resistant organisms, the infection remained uninfluenced by the further administration of streptomycin.

Streptomycin in Surgical Infections.—*Pulaski* and his associates say that the sulfonamide drugs, penicillin and streptomycin are by no means solely responsible for the reduced mortality in peritonitis. The management of peritonitis now includes, in addition to chemotherapy and antibiotic therapy, intestinal decompression, correction of fluid and electrolyte balance and of protein depletion and measures to prevent or treat thrombophlebitis and phlebothrombosis with threatening pulmonary infarction and embolism. The 63 cases of peritonitis which are reported form a heterogeneous group in respect to etiologic basis, management, dosage and duration of therapy. All the patients were desperately ill, but they were predominantly young men in good health. Of the 5 deaths, 3 were due to nonbacterial causes. In the other 2 cases streptomycin was added to other forms of therapy when the patients were already moribund. Eighteen of the 58 patients who recovered were treated only with streptomycin; the remaining 40 patients were treated with streptomycin and penicillin, supplemented in 10 cases by sulfadiazine. Immediate dramatic results were seldom observed following the administration of streptomycin, whether it was used alone or in combination with penicillin, although in both spreading and localized peritonitis recovery was thought to be more smooth and rapid when the drugs were used in combination. Resolution of peritoneal suppuration in the streptomycin series was of approximately the same pattern as is seen in patients receiving penicillin in excess of 800,000 units. Results were generally less striking when streptomycin was employed in infections which had already localized. The dosage of streptomycin varied between 1 and 4 Gm. per day, administered by the intramuscular route in divided doses at intervals of three or four hours. In a few instances streptomycin in amounts up to 0.5 Gm. was introduced into the peritoneal cavity at the time of operation. Consistently beneficial effects could never be attributed to streptomycin when the dosage was 2 Gm. per day or less. Harmful effects were not observed in consequence of daily dosages of 3 Gm. per day for ten to fourteen days, although minor untoward reactions occurred in approximately 20 per cent of the cases. Patients who received 3 Gm. per day of streptomycin alone or 2.5 Gm. in combination with an average of 480,000 units of penicillin had the most satisfactory postoperative convalescence. Streptomycin is not a panacea, yet it has a valuable place in the treatment of peritonitis.

Pulmonary Arteriovenous Aneurysm.—*Watson* states that the medical literature contains reports of only 10 cases of congenital or nontraumatic pulmonary arteriovenous aneurysm. The lesions have been reported as cavernous hemangioma of lung, multiple pulmonary hemangiomas and arteriovenous fistula of lung. As the gross anatomic structure consists of a lobulated, thin-walled, branching, blood-filled pulsating pulmonary sac made up of both an arterial and a venous component, it seems more logical to call these lesions pulmonary arteriovenous aneurysms in order to distinguish them from benign hemangiomas of the lung, metastatic pulmonary hemangiomas or hemangioendotheliomas of the lung. A pulmonary arteriovenous aneurysm produces a shunt whereby a considerable amount of blood passes from the arterial to the venous circulations of the pulmonary circuit without passing through the alveoli of the lung to be oxygenated. This results in a low oxygen saturation of the arterial blood. A patient so afflicted is in danger of hemorrhage which may prove fatal, of cerebral thrombosis with epileptiform seizures due to the slowed circulation and of increased volume in red blood cells. Coronary artery thrombosis is also known to occur. A mild degree of invalidism necessitating curtailment of activities is usual. Six patients have been cured by surgical measures. The histories of 2 of these are reported. Surgical measures varying from pneumonectomy, lobectomy and multiple local excisions to ligation of the offending, or "feeder," artery have been carried out, and there have been no postoperative fatalities. The untreated or medically managed patients have not improved or have died. Although pulmonary arteriovenous aneurysm is apparently a congenital lesion, symptoms may not appear until the age of 14 or 16 years. In 1 of the author's cases, the patient had reached the age of 27 and the lesion was causing no symptoms and was discovered by chance radiography. The diagnosis is suggested by a syndrome characterized by cyanosis, clubbing of the fingers and toes, secondary polycythemia and symptoms of anoxemia, usually in a young patient with an obscure pulmonary tumor and a normal heart. A bruit may be heard over the tumor. A gradual, expansive enlargement and thinning out of the walls of the vascular tumor probably takes place slowly over a period of years, and spontaneous hemorrhage occurs, as in case 2 of this report, when some slight overexertion increases the intrapulmonary pressure enough to cause a break.

Local Penicillin in Bronchopulmonary Suppurations.—Métras and Lieutier say that after using Thomson's catheter for bronchography, one of them designed a set of special radiopaque rubber catheters which allow the injection of radiopaque substances not only into a lobe but even into separate and selected bronchopulmonary segments. After they had used the special catheters for bronchography, they used them also to inject penicillin directly into a pulmonary abscess by way of the tracheobronchial tree. The tracheobronchial tree is first anesthetized with a 1 per cent solution of pontocaine hydrochloride and the catheter is introduced into the trachea. The patient is placed behind the fluorescent screen, then the catheter is directed toward the bronchus of the diseased segment and placed as near as possible to the bronchus of drainage. The patient is then placed in such a position that the end of the sound and the affected segment are vertically downward. The patient is arranged comfortably in this position, and 100,000 units of penicillin in 5 to 10 cc. of isotonic sodium chloride solution are injected slowly; the patient remains in the same position for thirty minutes The injection should be repeated every two days. The average number of injections needed is eight. For the bronchi of the middle and lower lobes the ordinary bent catheter is adequate; for the bronchi of the upper lobes it is necessary to use catheters with a double turn if an adequate injection is to be achieved. Sixty-three patients have been treated. The results show that local instillation of penicillin is worth while either because it provides an easy and quick method of improving the condition of the patient before operation or because it can cure with little disturbance and few manipulations many patients who would otherwise be judged hopeless. In the series of 63 cases, 75 per cent recovered and 17 per cent have undergone an operation for extirpation of the disease.

*Ascorbemia in Pulmonary Tuberculosis. Lafontaine.—p. 499.

Penicillin in Agranulocytosis.—Muller and his co-workers report the occurrence of agranulocytosis of the type of Schultz's disease in a man aged 46 with sore throat who presented symptoms of severe infection. His general condition was grave; there was pronounced asthenia and rise of temperature to 104 F. (40 C.). Nondiphtheric false membrane covered pharyngolaryngeal necrotic ulcers. Icterus occurred in the absence of hypertrophy of the hematopoietic organs and the liver Leukopenia (1,250 white blood corpuscles) associated with a nearly total disappearance of granulocytes (5 per cent) was demonstrated on hematologic examination. Sulfathiazole and antidiphtheritic serum were ineffective. Penicillin treatment was instituted with doses of 480,000 to 800,000 units per day by intramuscular route and was continued for twenty-five days; the total dose amounted to 12,970,000 units. This was combined with injections of pentose nucleotide and liver extracts. Following the start of the penicillin treatment, there was a drop in the temperature, which was gradually restored to normal. The general condition improved considerably. Regeneration of the blood progressed rapidly, thus demonstrating that the bone marrow was damaged but not destroyed anatomically. It may also explain the late occurrence of a secondary abscess of the submaxillary glands associated with polynucleosis warranting a favorable prognosis. Progressive improvement has continued for several months, suggesting a definite recovery with little risk of recurrence.

Ascorbemia in Pulmonary Tuberculosis.—Lafontaine determined the excretion of ascorbic acid in the urine, the level of ascorbic acid in the blood and the excretion of ascorbic acid in the urine after the administration of massive test doses of ascorbic acid (vitamin C) in 172 patients with pulmonary tuberculosis and in 20 healthy persons who lived under the same conditions, were placed on the same diet and were given the same amount of rest as the patients with tuberculosis. Results demonstrated a disturbance of the metabolism of ascorbic acid in the tuberculous patients; it was manifested by a decrease of the excretion of ascorbic acid in the urine, by a diminished level of the ascorbemia and by an increase in the retention of the agent following the administration of excessive test doses of ascorbic acid. Graphic records of the ascorbemia after the intravenous injection of ascorbic acid showed that the disturbance of metabolism is one of increased want rather than one of absorption or of excretion. The increase in the necessary amount persists in spite of the administration of massive doses of ascorbic acid. To some extent the disorder may be attributed to the tuberculous condition. The disturbance of excessive consumption of ascorbic acid is the more pronounced the severer the patient's condition, with the exclusion of other phenomena which may have an effect on the metabolism of ascorbic acid. There was no evidence of any therapeutic effect of ascorbic acid on the pulmonary tuberculosis or even on the hemoptysis.

Etiology of Toxemia of Pregnancy.—Edlén and his associates studied the relation between toxemia and blood groups in mother, father and child in 129 recent pregnancies. In the 31 cases in which the father had group O blood toxemia occurred in only 1 case; in the 59 in which both partners belonged to the same blood group and in the 7 in which the mother's blood group was AB it did not occur. These pregnancies are regarded as homospecific, other pregnancies as heterospecific. Toxemia of pregnancy occurred in 7 of 10 cases of heterospecific pregnancy in primiparas and in 4 of 22 cases in multiparas. The father's blood group, unless the mother belongs to the AB group, plays a decisive part in the origin of toxemia. The occurrence of toxemia probably depends on two factors, the hypophysis-thyroid hyperfunction normal in all pregnancies and a foreign factor; this latter factor, the authors maintain, is heterospecific protein transmitted from the father. Toxemia of pregnancy is thus regarded as an allergic reaction of the mother's organism to foreign protein. The results of attempts at prophylactic desensitization of the mother in heterospecific pregnancies by intracutaneous injection of the father's serum will be published later.

Orienting the New Employee in Services of Industrial Health Department. Jean S. Felton.—p. 519.
*Causalgia. P. Pernworth.—p. 525.

Causalgia.—Pernworth says that industrial surgeons are occasionally confronted with the apparent paradox of minor trauma producing severe subjective complaints. When the patient's symptoms greatly exceed the objective observations it is usual to give at least tacit consideration to some element of malingering. However, there is one well established syndrome which may follow insignificant injury. To this condition of autonomic derangement have been applied the terms reflex sympathetic dystrophy, causalgia or Weir-Mitchell's syndrome. When bony changes are prominent the phenomenon is termed Sudeck's atrophy. Whenever sympathetic dystrophy is suspected, a block of the autonomic nerve supply to the affected area should be induced with procaine hydrochloride. Response to anesthesia of the involved sympathetic ganglion is a reliable diagnostic criterion of this condition. The author illustrates this by a case report. He concludes that causalgia should be considered as an etiologic factor in all chronically painful limbs that show vasomotor changes.

*Bacteriologic Findings in Undifferentiated and Other Acute Respiratory Diseases. J. H. Dingle, T. J. Abernethy G. F Badger and others.—p. 465.

Clinical Patterns of Acute Respiratory Diseases.—Dingle and his co-workers present a classification of acute respiratory disease as it occurred among recruits in the army during three years of observation. From 75 to 90 per cent of all respiratory admissions to the hospital were due to a syndrome of undifferentiated acute respiratory disease. The average clinical pattern of this syndrome did not change in three separate studies in different seasons. The cases were characterized by a short febrile course and presented a combination of general constitutional symptoms with a prominence of symptoms suggesting involvement of the tracheobronchial tree. Symptoms of nasal involvement were less common. It was a disease without characteristic physical observations and with a normal leukocyte count. Its etiology was unknown. There was no suggestion of a bacterial cause and much to suggest a virus etiology. Exudative tonsillitis and pharyngitis was responsible for 10 to 15 per cent of respiratory admissions. In half of the cases, beta hemolytic streptococci were not found. These cases not due to streptococci had a rather characteristic pattern of symptoms and of physical signs in the throat. They were not dissimilar from cases of undifferentiated acute respiratory disease, of which they may be a variant. In the remainder of the cases of exudative tonsillitis and pharyngitis the throat harbored beta hemolytic streptococci. In some of these streptococcic antibodies developed. The latter cases conformed to a pattern of symptoms and physical signs which was distinctive and set them apart from all the other groups. The remainder were cases in which diagnostic antibody responses did not develop. Some were probably true streptococcic infections, but most resembled nonstreptococcic exudative tonsillitis and pharyngitis superimposed on a streptococcic carrier state. Only a small part of the total admissions for acute respiratory disease was made up of primary atypical and bacterial pneumonias and a miscellaneous group of other respiratory infections.

Bacteriologic Data in Acute Respiratory Diseases.—Dingle and his co-workers agree with Bloomfield that the most efficient method of studying the relationship of minor respiratory disease and the bacterial flora of the respiratory tract is by taking serial cultures before, during and after colds, employing the same subjects repeatedly over a period of time. Human volunteers were subjected to inoculation with infectious material, and bacteriologic observations were made at two day intervals throughout prolonged preinoculation and postinoculation periods. No changes in flora were noted during illness which were greater than those seen in the same persons before illness or in other persons not inoculated. In a similar manner serial throat cultures were obtained from several platoons of army recruits. Evidence was not obtained that changes in bacterial flora occurred in relation to the onset of colds. In both studies considerable variation was observed in the carrier rates of several organisms grown from these cultures These variations were not related to the development or to the general prevalence of minor respiratory illness. Throat cultures of men hospitalized for undifferentiated acute respiratory disease and influenza revealed no differences which could be associated with their illnesses, in contrast to results in those with infections due to beta hemolytic streptococci.

Diarrhea of the Newborn.—Clifford shows that the emergence of epidemic diarrhea in the newborn as a public health problem coincides with the transfer of childbirth from the home to the hospital. Hospitals have been unprepared for this migration, and crowding infants into nurseries, in addition to the shortage of personnel, has produced conditions favorable for the spread of infection. There is a national need for more beds for obstetric patients and for more nurseries, each to be limited to 8 to 12 newborn infants. In five epidemics a specific virus etiology has been proved. This virus is probably the cause of other outbreaks, but many epidemics of diarrhea in the newborn have been traced to a variety of pathogenic organisms that could only reach the infant by the fecal-oral route. In a large percentage of these outbreaks investigators have found evidence of gross breaks in nursery technic. The first obligation is to block all routes by which the infant can acquire bacterial infection in the nursery through a strict application of known nursery and formula-room technics.

Headache: Impressions of an Ophthalmologist. F. D. Carroll.—p. 503.

Occupational Strain and Rectal Conditions.—Zager says that some standard textbooks, specifically Bacon, mention as predisposing to hemorrhoids "severe muscular strain such as lifting" and increased intra-abdominal pressure such as "straining from coughing, sneezing and vomiting." Authorities considered procidentia of the rectum a form of "sliding hernia," and for this reason its parallel to the compensable situation of inguinal hernia is not too far fetched. The author relates histories of 3 workers in whom rectal symptoms appeared after heavy lifting or pulling and who were granted compensation. He thinks that preemployment physical examination should be more carefully performed to rule out the possibility of preexisting disease of the rectum. The Workmen's Compensation Act pays for aggravation as well as for direct cause.

Book Notices

Gastroenterology in General Practice. By Louis Pelner, M.D., Associate Attending Physician Greenpoint Hospital, Brooklyn With the collaboration of Louis A Held, M D, Attending Roentgenologist, Beth Moses Hospital, Brooklyn and contributions from Alexander Lewitan, M D, Consulting Roentgenologist Norwegian Public Health Service, New York, Samuel Waldman, M D, Associate Attending Physician, Greenpoint Hospital, Brooklyn, and Siegfried W Westing, M D, Roentgenologist, Brooklyn Cancer Institute, Brooklyn Fabrikoid Price, $7 50 Pp. 285, with 109 illustrations Charles C Thomas, 301-327 E Lawrence Ave., Springfield, Ill, 1946

The aim of the author as stated in the preface is to make this "an every day hand-book rather than a complete reference work" While he succeeds in accomplishing this purpose there is probably little need for such an elementary book in the library of the general practitioner Any standard textbook of general medicine will supply all that is found in this book plus fairly complete descriptions of the other common diseases encountered in medicine The chapters on psychosomatic problems are well written and will be of value to the practitioner.

Walk with a Separate Pride. By Sheila Alexander Cloth, Price, $2 50 Pp 158 The Itasca Press, a division of The Webb Publishing Co 55 E Tenth St, St. Paul 2, 1947.

The author of this book was seven months pregnant when her husband left for the wars Her book is a psychologic document, imaginative, poetic and sensitive. As fiction it will appeal to few readers. As a contribution to the stream of consciousness, it will be of special interest to the psychologists and the psychiatrists.

The American Sanatorium Association: A Brief Historical Sketch. By Lewis J Moorman, M D Historical Series Number 3. Paper. Pp 72, with portraits. National Tuberculosis Association, 1790 Broadway, New York 19, 1947.

This booklet presents a historical account of the development and organization of the American Sanatorium Association, now known as the American Trudeau Society Included is a record of its meetings and transactions since the establishment in 1905, giving not only a list of committees and their functions, papers, discussions and other activities, but also the names of physicians who have taken a prominent part in the work of the association. As these events and activities unfold, the reader will gain a clearer understanding of the progress that has been made in the sanatorium field since the turn of the century. The booklet will be of interest to physicians associated with sanatorium services as well as to others who are concerned in the treatment and care of those with tuberculosis.

Office Treatment of the Eye. By Elias Selinger, M.D., Attending Ophthalmologist, Mount Sinai, Cook County and Michael Reese Hospitals, Chicago Cloth Price $7 75 Pp 542, with 67 illustrations. Year Book Publishers, Inc, 304 S Dearborn St, Chicago 4, 1947

Since probably 90 per cent of most ophthalmic practice is office practice, this textbook contains much the same material that is to be found in good textbooks of ophthalmology except for major surgical problems. The important difference is in the approach to the subject and the difference in stress on various phases. There is little anatomy and not much that could be considered primarily instructional at the level of the undergraduate medical student It is assumed that the reader is grounded in the fundamentals though the more abstruse problems, such as those concerning the handling of the extraocular muscular abnormalities, are considered in great detail The book tends to be a treatise on therapy and is up to date along these lines. The writer is rather conservative in his advice, the book being free from radical suggestions The average ophthalmologist will probably not find much that is new to him but will enjoy the easy readability and sound advice The illustrations, printing and format are acceptable The book can scarcely be considered a "must" for the practicing ophthalmologist but rather a pleasing addition to his ophthalmic library

Studies in Genius. By Walter G. Bowerman. Cloth. Price, $4.75. Pp 343. Philosophical Library, Inc., 15 E. 40th St., New York 16, 1947

After defining genius, the author analyzes the list of eminent Americans *as to their birthplace, heredity, marriage, height and* weight, cause of death and similar factors. Among 973 eminent Americans he includes twenty-four physicians, and as to the genius of some of them there might be considerable doubt. The book presents some interesting speculations but little that can be practically helpful in selecting and encouraging genius.

The Science Digest Reader: A Selection of Outstanding Articles Published in Science Digest During the Past Ten Years. Cloth Price, $3. Pp. 310 Windsor Press, 200 E Ontario St, Chicago 11, 1947.

From the periodical called *Science Digest* the editors have selected a number of articles published during the past ten years. A few are in the field of medicine, for example, "Foolish Fancies About Your Health," "The Gifted Child," "Your Stomach Is Really a Gland" and "Childbirth Without Pain." Several of the articles are republished from *Hygeia.*

How Our Minds Work. By C. E. M. Joad Cloth Price, $2 75 Pp. 110. The Philosophical Library, Inc., 15 E 40th St, New York 16, [n. d.].

Innumerable books have been published recently trying to *explain modern psychology to the average reader. Influence* of the mind on the body is now generally accepted, and psychosomatic medicine has a well recognized position in medical circles. Dr. Joad's book is an exceedingly brief analysis of current points of view and quite inadequate in simplifying for the general reader the controversies that prevail in modern psychology and psychiatry. He concludes by insisting that the unconscious is not nearly as important as the psychoanalysts insist, but he recognizes that some extraordinary results have been achieved by psychoanalytic methods.

Reading and Visual Fatigue. By Leonard Carmichael, Ph.D., President, Tufts College, and Director, Tufts Research Laboratory of Sensory Psychology and Physiology, Medford, Mass., and Walter F. Dearborn, M.D., Ph.D., Director, Psycho-Educational Clinic, and Professor of Education, Harvard University, Cambridge, Mass. Cloth. Price, $5. Pp. 483, with 103 illustrations. Houghton Mifflin Co., 2 Park St., Boston 7, 1947.

A committee of well known scientists and educators, known as the Committee on Scientific Aids to Learning, financed a series of investigations of reading. These began in 1940 at Harvard University and Tufts College and were continued by *one of the investigators at the University of Rochester.* Special types of apparatus were developed for recording eye movements.

Modern industrial and educational processes place a tremendous burden on vision. Some physicians have even credited continuous, fatigue of the eyes with being the foundation of the "neurotic tendency" of our times. After a definition of visual fatigue the authors present their consideration of the factors involved in reading and the relation of these factors to fatigue. The technic of the experiments is described in detail, followed by a discussion and interpretation of the results. An excellent summary and conclusions provide the general reader with the true significance of the study

Apparently one may assume that the total visual mechanism is able to function approximately as effectively at the end of a long period of continuous activity—as much as six hours—as at the onset of that activity. An analogy is made with the heart The heart muscle can recuperate in the short time intervals between its contractions. When needed, the heart can rise to new levels of activity. Proper athletic training assists in conditioning the heart and the circulation for the new effort. The factors of safety in the construction of the eye are great, and its muscles are larger and stronger than necessary for most of the movements that the eye may make This leads to the conclusion that the long periods of study required of high school and college students are not injurious to their eyes. The final conclusion of the authors is also important. The first index of fatigue comes in alterations of the general attitudes and general feelings of the person concerned rather than in a breakdown of the sensory neuromuscular mechanism which actually performs the task.

The Master Hand: A Study of the Origin and Meaning of Right and Left Sidedness and Its Relation to Personality and Language. By Abram Blau, M.Sc., M.D., C.M., Assistant Clinical Professor of Psychiatry, New York University College of Medicine, New York. Research Monographs No. 5, American Orthopsychiatric Association, Inc. Cloth. Price, $4.50. Pp. 206, with 13 illustrations. The American Orthopsychiatric Association, Inc., 1790 Broadway, New York 19, 1946.

The subject here considered has attracted much scientific attention in recent years. Some of the author's conclusions may still be debatable. He does not find that preferred laterality or the preference for either the right hand or the left hand is inherited. He considers it a complicated developmental psychologic trait. Evidence indicates that preferred laterality is manifested not only between hands but between eyes, legs and other human functions. Some persons prefer to walk on one side of the street rather than the other. Few ambidextrous persons indeed are equally competent on both sides. Animals do not show preferred laterality as do human beings. In human beings the preference for the right side is a cultural and social convention. An infant does not have any preference for one side or another, but our environment is built on righthandedness and preference for one side or another usually becomes apparent at about 9 months of age. Lefthandedness represents a failure to learn righthandedness, according to the authorities. Any physical defect in the right hand enforces use of the left. Lefthanded parents are unconsciously models for lefthanded children. The author believes that the commonest type of lefthandedness is due to emotional contrariness in early childhood. Cerebral dominance is related to handedness, so that persons are leftbrained because they are righthanded. The author recommends that children be encouraged in their early years to adopt righthandedness because thus the child will be better equipped to live in a righthanded world. He does not believe that there is any danger in restraining or retraining children in handedness. The most he finds that is required is careful and sympathetic training in the use of the other hand with proper directional orientation.

Your Teeth: And How to Keep Them. By Jerome J. Miller, D.D.S. With an Introduction by C. Raymond Wells, D.D.S., Sc.D., Captain, Dental Corps, U. S. Naval Reserve. Cloth. Price, $3. Pp. 232, with 44 illustrations. Lantern Press, Inc., 257 Fourth Ave., New York 10, 1947.

This volume, written by a practicing dentist and teacher of dentistry, attempts to present intelligibly answers to questions about teeth and their care to the lay reader. While the book is intended primarily for the nonmedical person, it may have real usefulness to the physician in interpreting such material to his patients.

Facts about the structure and growth of teeth are introduced in relation to proper care and as a background for good oral hygiene. Common dental problems that arise at various age levels are discussed with special attention to the care of children's teeth. The author refutes the general belief that there are "hard and soft teeth" and makes a strong case against "fear of dental pain" in view of local and general anesthetics, drugs to calm the highly nervous person and advances in dental technic. Restorative dental treatment and appliances are dealt with at some length, with skilled dental service rather than the appliance receiving major emphasis. Simple cleansing of the teeth together with regular dental care are stressed as important principles of dental health

The book is written in understandable language, and is illustrated with line drawings where graphic clarification seems valuable. The author has honestly labeled theories as such, has been careful in interpreting facts and has not hesitated to admit limitations of present knowledge.

Overcoming Stammering. By Charles Pellman With a foreword by Dr. Frederick Martin. Cloth. Price, $3. Pp. 160. The Beechhurst Press, Inc., 296 Broadway, New York 7, 1947.

This book attempts to present a practical system for the treatment of the stammering child. The terms stammering and stuttering are considered synonymously in the text. The author, a practicing speech correctionist, advocates reconditioning the speech reflexes, contending that stammering must be overcome by developing the faculty of speech itself. He takes issue with those who look on stammering as the symptom of an inferior nervous constitution and with those who seek to achieve correction solely through public speaking, breath control or word substitution and the like.

The method involves learning speech over again, in an objective way, following essentially the same steps by which a child learns to talk. Fundamental and auxiliary drills are employed, and a partial silence to allow for the setting of new speech responses is a part of the procedure. Tongue, facial and general physical exercises are used to break down muscular rigidity. A great deal of attention is given to dispelling speech consciousness and the fears which beset the stammerer. Emphasis is placed not only on eliminating the defect but also on aiding the child to become a proficient speaker. A portion of the book is devoted to suggestions as to how the intelligent parent can help in the process.

The theories presented, stressing correction primarily through reconditioning speech patterns and improving mental hygiene, should be of interest to parents, teachers and physicians concerned with this problem.

Digitalis and Other Cardiotonic Drugs. By Eli Rodin Movitt, M.D., Captain, Medical Corps, Army of the United States. Cloth. Price, $5.75. Pp. 204, with 15 illustrations. New York: Oxford University Press, 1946.

An excellent summary of the present day information on digitalis and related compounds is given in this small and readable book. The various components of digitalis are reviewed in detail, starting with a brief historical account of the fractions the structural chemistry, specific pharmacologic properties and clinical experiences. A number of diagrams throughout the book clearly illustrate some of the aspects of the digitalis fractions that are confusing to the average practitioner. Basic chemical reactions and structural formulas afford the reader an opportunity to see the latest developments in the field of glycosides and materially clarify parts of the text that would otherwise be of benefit only to research workers in the field of cardiology. A number of graphs demonstrate pharmacologic action in terms of energy liberation, work performance, efficiency of operation, pulse, heart volume and absorption and elimination of the various drugs. It is to be regretted that there are few electrocardiograms shown on pages 80, 99 and 105 and those few rather poorly printed.

The discussion on strophanthus, squill, thevetin and other drugs of plant and animal origin is accurate and well written. A number of minor errors unfortunately appear in the book, as venus pressure on page 9. Some will question the unqualified statement on page 25: "One should remember that in acute myocardial infarction the displacement of the RS-T segment takes place in the opposite direction (above the iso-electric line) from that observed in digitalis effect." On the whole, it is an excellent book on digitalis and allied substances that should be of real value to the general practitioner and the internist. An excellent review of the literature, a well prepared bibliography and a good index enhance the usefulness of the book, which is basically a fair statement of present knowledge of the subject in easily readable and enjoyable style.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

DIPHTHERIA VIRULENCE

To the Editor:—We frequently hear of "diphtheria carriers" held for weeks or months of observation on account of suspicious diphtheroids as visualized on smear by some technician. In many of these cases the faucial lesion or membrane and/or the clinical course or therapeutic response are not especially typical of infection due to Corynebacterium diphtheriae. I would appreciate answers to the following questions: 1. Does a microscopic smear ever justify a positive differential diagnosis between a true virulent diphtheria and a nontoxic diphtheroid? 2. Can a positive statement as to the degree of virulence be justified from rough or smooth appearance of the culture? 3. Can the same organism, found to be nontoxic by guinea pig inoculation on one occasion, be capable of changing its virulence after repeated cultures or after repeated animal or human passage? 4. Should inoculation of toxin for virulence in guinea pigs be mandatory in the study of all cases of diphtheroid? 5. What is the latest thought regarding the value of the tellurite technic relative to virulence of diphtheria and diphtheroid organisms?

M.D., North Dakota.

ANSWER.—1. One experienced in the examination of diphtheria organisms can differentiate on smear, in the vast majority of instances, between a true diphtheria bacillus and a diphtheroid. However, it is not possible to distinguish by smear examination the difference between virulent and nonvirulent diphtheria bacilli. 2. No. 3. Yes. 4. If it is determined to one's satisfaction that the organism is a diphtheroid, a virulence test would not be necessary. 5. The tellurite technic would be of no value for determining the virulence of diphtheria organisms.

ACNE

To the Editor:—Kindly outline the latest treatment of acne simplex and acne vulgaris in an adolescent male aged 19. Is roentgen treatment preferable to cold quartz? Do emotional factors play a part?

M.D., New York.

ANSWER.—Treatment in these cases depends on the severity of the acne. If the lesions are superficial, small and not too disfiguring, satisfactory results can be obtained by a combination of topical therapy and some simple dietary restrictions. A sulfur preparation such as lotio alba should be applied every night to the point of producing slight exfoliation. The patient should be instructed to avoid the following in his diet: seafoods; foods that produce flushing of the skin, such as hot dishes, spices and alcohol; foods rich in fats, particularly chocolate, cheese, nuts, fat meats and gravy. The face should be cleansed thoroughly with soap and water two or three times a day, and the patient should not engage in an occupation which exposes him to oils or greases. If there is constipation or anemia, these should be brought under control. In recent years vitamin A, vitamin B, thyroid substance and estrogenic substance have been recommended, but their efficacy is still a matter for debate. Blackheads should be removed by the proper expressor and cystic lesions should be incised with a very small blade, as an iris knife. For persistent, deep-seated lesions roentgen therapy is still the treatment of choice and is preferable to use of the cold quartz mercury vapor lamp. The influence of emotional factors usually is not great; rather, acne is likely to affect the emotions.

LEUKEMIA

To the Editor:—Has leukemia, especially acute lymphatic leukemia, ever been produced experimentally? Is there a cerebral center which regulates formation of blood, especially white blood cells? Can this center be disturbed by trauma or regulated by drugs?

M.D., Pennsylvania.

ANSWER.—Leukemia of all types (lymphatic, myelogenous and monocytic) has been produced experimentally in mammals by numerous agents including radiation, hormones and various chemicals. It also occurs spontaneously in many animals. The picture resembles more the chronic leukemias in the human. In chickens there is a spontaneous disease, similar to human leukemia, caused by a virus.

The existence of a cerebral center for the regulation of blood formation has never been established, although there have been speculations as to the role of the pituitary and hypothalamus. The possible effects of drugs or trauma on such a hypothetic center would therefore be a matter of conjecture only.

Forkner quotes four authors who each described acute leukemia following injury to bones. However, the available evidence for a cause and effect relationship does not seem to be clearcut.

CESAREAN SECTION

To the Editor:—The general opinion is that it is "not safe to have more than two caesarian sections"—hence sterilization is performed routinely at the second section. Further, "once a section, always a section," regardless of normal pelvis, position. Is this correct?

M.D., Arizona.

ANSWER.—Theoretically each additional pregnancy after cesarean sections might involve increased risk of rupture of the uterine scar, and the operations might become more and more difficult because of adhesions; in practice, however, the likelihood of these accidents is minimal with laparotrachelotomy. Ordinarily there is no limit to the number of sections which a healthy woman may safely undergo. As many as eight sections have been done on some patients.

Sterilization is obviously indicated in a patient suffering from some condition such as grave cardiac or renal disease, which would make another pregnancy hazardous. It may also be considered as an elective procedure at the second or a later caesarean section in a healthy woman if she and her husband decide, after mature consideration, that their desire for another child is not great enough to warrant the ordeal of a laparotomy.

The dictum "once a cesarean, always a cesarean" holds good when the first operation is done for contracted pelvis or some other abnormality which would equally complicate all subsequent deliveries. But if the first section is performed because of a condition incidental to that one pregnancy, for example, placenta previa or preeclamptic toxemia, it is frequently possible for later deliveries to be effected from below, especially if the patient has already borne a child *per vias naturales.* Labor in such a case should be watched with special care, and everything should be ready for laparotomy if there is any indication of thinning of the uterine scar.

"DICUMAROL"

To the Editor:—The administration of "dicumarol" for a relatively prolonged period of time is sometimes indicated. There are many disadvantages such as the necessity for the periodic determination of prothrombin levels, which is costly. This drug is primarily for the purpose of reducing the coagulability of the blood. Is it a more rational and practical procedure to regulate the dosage of the agent by determining the coagulability, rather than the prothrombin activity, of the blood?

M.D., Illinois.

ANSWER.—Determination of coagulation time cannot be substituted for that of prothrombin time in regulating the dosage of "dicumarol," because the coagulation time is little affected at the level of prothrombin (20 per cent of normal), which is desired for therapeutic effectiveness. It is only when the prothrombin is reduced to an exceedingly low concentration that a significant prolongation of the coagulation time occurs (Quick, A. J.: *J. Biol. Chem.* **161**:33 [Nov.] 1945).

Even if the coagulation time was suitable for testing quantitatively the action of "dicumarol," the obstacle of trustworthy technic still remains. The determination of the coagulation time by the capillary method, as commonly carried out, is meaningless and worthless. Only when the determination is performed by the Lee White technic under carefully controlled conditions are reliable results obtained; and this entails practically as much skill and effort as the prothrombin time method. The prothrombin test remains the only trustworthy means to control "dicumarol" therapy. Since it is becoming a routine hospital laboratory procedure, it should soon become available to most physicians.

FURUNCULOSIS

To the Editor:—For two years I have been treating a girl aged 4 years for repeated attacks of furunculosis. Sulfonamide drugs and penicillin (both internally and externally), a full course of autogenous vaccine and staphylococcus endotoxoid have been used without effect. Furuncles continue to develop every few months. Foci of infection are absent. Urinalysis is normal. Her health is otherwise good. Her parents are in good health. Please suggest other methods of treatment.

Jacob Greenblatt, M.D., Stamford, Conn.

ANSWER.—Occasionally, satisfactory results are obtained by the simple procedure of having the patient's entire body sponged twice a day with a solution of bichloride of mercury, 1 : 10,000. The underclothing should be changed daily and the outer clothing cleaned frequently. Generalized ultraviolet baths are often helpful, and the intake of carbohydrates should be restricted. One must be certain that the child is not receiving bromides or iodides, which occasionally will produce furunculous lesions in sensitized persons. A sugar tolerance test might reveal useful information.

If in spite of this regimen a new outbreak of furunculosis should occur, it might be well to administer penicillin again in large amounts and for a longer period, along with roentgen therapy to the lesions.

SYPHILIS

To the Editor:—A boy aged 16 had a severe attack of acute rheumatic fever at the age of 10 years. He was confined to bed for six months. Wassermann examination at that time revealed a 4 plus reaction. Examination since that time reveals no signs of syphilis other than positive blood tests. Serologic tests for syphilis on the blood and spinal fluid of the mother and on the blood of two other children in the family have been negative. The father of the patient died with Hodgkin's disease. The patient had recurrent acute rheumatic fever two years ago, but the attack was mild and there is now no evidence of rheumatic fever. Repeated Kolmer and Kahn tests on the blood of the patient have been strongly positive. Should he be told that he has a false positive test, or should antisyphilitic treatment be administered and a quantitative Kahn examination of his blood be made at regular intervals? M.D., Texas.

Answer.—It is stated that the examination does not reveal signs of syphilis. Was a lumbar puncture done? Moreover, it is not stated how many units of reagin were present in the patient's blood. In certain diseases with reversal of the albumin globulin ratio, e. g., granuloma inguinale, lymphogranuloma venereum and subacute disseminated lupus erythematosus, a false positive serologic test for syphilis occasionally occurs.

This patient should have a lumbar puncture, and if that is negative, much would depend on the degree of positivity in terms of Kahn units. One would hesitate to treat the patient for syphilis unless the test showed a high number of units. Occasionally a syphilis insontium does occur, and that must be considered as a possibility if the boy has a large number of Kahn units. Under those conditions, it might be well to give this boy, after a short course of intramuscular injections of bismuth subsalicylate, once a week for six or eight weeks, a course of crystalline penicillin G, 7,200,000 units, the injections being given intramuscularly every three hours over a period of two weeks.

REFRIGERANT GASES

To the Editor:—Please give me information regarding the toxic effects, if any, resulting from gases used in refrigeration, namely, methyl chloride and dichlorofluoromethane. The patient is a maintenance and installation mechanic for refrigeration units.

Cecil C. Shaw, M.D., Loxley, Ala.

Answer.—Dichlorodifluoromethane, known under the trade name of "freon," is a colorless, nontoxic refrigerant. R. R. Sayers, W. P. Yant, J. Chornyak and H. W. Shoaf (Industry Report 3013, United States Department of Commerce, Bureau of Mines, May 1930) report on the toxicity of dichlorodifluoromethane as follows "In so far as the results of animal experimentation serve as a measure of hazards to persons, the investigation has shown that the possibilities of public health and accident hazards resulting from exposure to dichlorodifluoromethane when used as a refrigerant are remote."

Methyl chloride as used in the refrigeration industry is a colorless liquid with an ethereal odor and a sweetish taste. It is inflammable and explosive as well as toxic. Acute poisoning is attended by headache, dizziness, mental confusion, nausea and vomiting, lowering of blood pressure and, in serious cases, cyanosis, cramps and coma. Chronic cases are characterized by increasing fatigue, lassitude, muscular weakness, restlessness and occasionally, insomnia.

Most cases of individual poisoning are due to repeated exposure to small doses which gradually cause injury to the central nervous system. Exposure to 200,000 parts per million for one hour is dangerous to life; exposure to 500 parts per million is a safe working condition for a few hours, according to California law.

CATARACT

To the Editor:—A patient has a mature cataract in the left eye and incipient in the right eye. Recently he consulted an oculist and was given the following treatment. Synthetic thyroxin (2 mg. to each cc. distilled water) to be dropped in eye three times daily. He was told that in many instances this would retard if not improve his condition. Please give information regarding this treatment.

Ralph C. Wise, M.D., Mansfield, Ohio.

Answer.—Thyroxin was first used in 1934 by Jameson on the theory that thyroxin exerted a local stimulating effect and acted as an alternative. His dosage was 1 mg. to the cubic centimeter used locally on the eyeball. He reported beneficial results both in limiting the growth of cataract formation and in the absorption of existing opacities. In 1941 Gillette repeated some of Jameson's work and did a series of his own; he came to the conclusion that thyroxin locally (1) does not check the development of senile lens opacities (2) does not cause the absorption of existing opacities and (3) has no demonstrable metabolic effect. Vail seems to be of the same opinion as Gillette. At the present time there seems to be little clinical evidence that thyroxin is of any use in preventing further growth of cataract or in absorbing existing lens opacities.

STERILITY

To the Editor:—I have a male patient, aged 40, with relative sterility. His history is essentially noncontributory, but he recalls that his left testicle was traumatized at 13 years of age. Physical conditions are normal except that the left testicle is about half the size of the right. Both testes are of normal consistency. The prostate is slightly enlarged and somewhat boggy. Results of urinalyses and the Wassermann test are negative. Hemoglobin and the white blood cell count are within normal limits. The basal metabolic rate is minus 12 per cent. The volume of ejaculated semen is about 2.5 cc., with a sperm count of 10 million. Motility of sperm is somewhat sluggish. I did not determine the percentage of abnormal forms, but on ordinary microscopic examination some abnormal spermatozoa are seen. I am treating this patient with vitamin E and thyroid. Is other therapy recommended? What are this man's chances of attaining a normal level of fertility?

M.D., Ohio.

Answer.—Before any elaborate program of treatment is undertaken, the cell structure of the spermatozoa should be evaluated. If there proves to be a high incidence of abnormal forms, then a biopsy of this patient's right testicle is indicated. This will help to judge whether the germinal epithelium is capable of responding to stimulation. The first step in treatment is careful attention to hygiene and general health, with special reference to outdoor exercise, rest and relaxation, adequate protein in the diet and the possibility of chronic focal infection. The prostatovesicular secretions should be examined.

Endocrine therapy deserves a trial, though results are often discouraging. Pregnant mare's serum, other chorionic gonadotropins and pituitary gonadotropins might be used seriatim, since there is no way of predicting which offers the best chances of benefit. While large doses of sex hormones inhibit the anterior pituitary, very small doses of testosterone sometimes readjust the pituitary-gonad balance in such a way as to increase the gonadotropic output.

A postcoital examination (Hühner test) done at the wife's midcycle will show how well the spermatozoa are able to invade the endocervical mucus. If a defect in this regard is observed, attention should be directed to possible abnormalities of the mucus, such as scantiness or infection, and appropriate treatment should be instituted.

Relative infertility in one partner may be overcome by high fertility in the other. Hence, the wife should be critically studied with the idea of finding and eliminating all factors of infertility.

Efforts to improve the values of deficient semen are usually attended by rather meager success. Nevertheless, definite improvement may be obtained in a few cases.

CORRECTION; PERTUSSIS VACCINE

To the Editor:—In the Dec. 13, 1947 issue of *The Journal*, page 1040, under "Vaccination against Pertussis," there is an error in the second paragraph on the dosage of Sauer pertussis vaccine alum precipitated.

The alum precipitated pertussis vaccine prepared according to the Sauer specifications contains 30 billion Hemophilus pertussis bacilli per cubic centimeter, and the recommended dose is 0.5 cc. per injection at one month intervals. Four injections are recommended if immunization is attempted before the sixth month of life, or three doses if injections are begun after 6 months of age. It is recommended that injections be made in the buttocks, alternating from left to right, care being taken not to make a second injection in a site previously used.

The dosage described in the article referred to is for the plain H. pertussis vaccine, which should be used only after the child is 6 months of age or older. When alum precipitated pertussis vaccine is administered in dosage greater than 0.5 cc. an area of softening may be caused by the alum, which is known as "alum cyst." Occurrence of such cysts is infrequent but can be avoided by using small doses of the vaccine.

Louis W. Sauer, Evanston, Ill.

PENICILLIN—STREPTOMYCIN

To the Editor:—On page 745 of the Nov. 15, 1947, issue of *The Journal* is an answer to a query which might well be further elaborated. It is true that, in general penicillin and streptomycin are compatible, at least as far as the antibiotics themselves are concerned. However, if streptomycin sulfate should be mixed with calcium penicillin, of which a significant amount is still sold, a precipitate of calcium sulfate would be inevitable. I thought it might be well to elaborate on this point, because otherwise some one might get an unwelcome surprise.

Robert D. Coghill, Director of Research,
Abbott Laboratories,
North Chicago, Ill.

POSSIBLE INCOMPATIBILITY OF STREPTOMYCIN AND PENICILLIN

To the Editor:—In the Nov. 15, 1947, issue of *The Journal*, page 745, I note that in answer to an inquiry concerning the possibility of giving streptomycin and penicillin in the same syringe the reply states that there is no incompatibility. I think the situation has been overlooked in which aqueous solutions of calcium penicillin and streptomycin sulfate might be mixed, with the consequent formation of calcium sulfate as an insoluble precipitate.

FIVE YEAR FOLLOW-UP OF GLAUCOMAS

PETER C. KRONFELD, M.D.
Chicago
and
H. ISABELLE McGARRY, M.D.
Evanston, Ill.

From the Illinois Eye and Ear Infirmary, University of Illinois.

Read before the Section on Ophthalmology at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1947.

To the almost innumerable reports on the effect of treatment on the course of glaucomas, another one is added herewith in the hope that it will justify its presentation by meeting more fully the requirements for such reports as set by Sidney A. Fox in 1943.[1] Those requirements were: (1) the adoption of a standard nomenclature for glaucoma, (2) the provision of a standard preoperative classification of glaucoma into groups and subgroups; (3) a systematic evaluation of all the important operative procedures, old and new, in all the common types of glaucoma, (4) a systematic follow-up for definite periods of time and (5) evaluation of results on the basis of generally adopted, uniform criteria.

While fulfilment of requirements 1 and 2 will be impossible until a representative, probably international committee of experts agrees on a standard nomenclature and classification of the glaucomas, we believe that the distinction between the narrow angle (iris block) and the wide angle type among the so-called primary glaucomas (O. Barkan[2]) expresses such a fundamental difference in pathogenesis and mechanism that, at present at least, it appears to be the most logical basis for classification. The fact brought out in this study that the results of treatment prove significantly different in the two types adds another piece of evidence in favor of this classification.

The surgical operations referred to in this report were performed by surgeons of such widely varying background and such different general attitude toward the problem of glaucoma that the net result as to choice of operation in the specific types and stages of the glaucomas came close to a systematic evaluation of all more common operations.

We believe that requirements 4 and 5 have been met in this report. The follow-up was made by the medical staff of the Glaucoma Clinic of the Illinois Eye and Ear Infirmary. The staff consists of two or three ophthalmologists whose training, experience and disposition qualify them for the job of objective, impartial observer and recorder in the follow-up of the glaucomas.

As criteria of the efficacy of the treatment, we have considered the course of the glaucomatous involvement of the optic nerve as disclosed by perimetry and measurements of visual acuity, as well as the ocular tension.

The specific object of this study has been the establishment of the relationship between the course of the glaucomatous involvement of the optic nerve and the prevailing range of tension in the various stages of glaucomas.

MATERIAL AND PROCEDURE

This report is based on the observation in the Glaucoma Clinic of the Illinois Eye and Ear Infirmary of definite (not borderline) cases of so-called primary glaucoma in adults. In accordance with the general plan of this study, the patients, or rather their individual eyes, were classified as to stage of the disease, course of the disease and prevailing tension range. Each eye was thus classified at the time when, as the result of treatment, the tension had become stabilized within a definite tension range, and again five years later. Only eyes which maintained this tension range—as evidenced by frequent tonometric readings during morning hours—for the entire period of five years were included in this study.

The classification as to the stage of the disease was based entirely on perimetric findings. Three stages: early, moderately advanced and far advanced, were distinguished. Because of a certain perimetric routine followed in the glaucoma clinic, it became advisable to modify the limits of Gjessing's[3] three groups as follows:

The limits of stage 1 (early glaucomas) were the perfectly normal field on the one hand and one to two, narrow, incomplete to complete Bjerrum scotomas (for 3/1000 white targets) with normal position of the isopter for 3/330 white on the other hand. The papilla was either not perceptibly altered or showed early glaucomatous changes.

Stage 2 (moderately advanced glaucomas) was characterized by a "merger" between the Bjerrum scotoma and the peripheral constriction on the nasal side resulting in extensive defects chiefly in the nasal half of the field. The nerve head showed definite glaucomatous changes.

Stage 3 (far advanced glaucomas) was considered to be present in the cases in which after loss of most of the nasal field the remaining portions had been invaded. The limits of this group were, on the one hand, a somewhat reduced temporal half with well functioning center and, on the other hand, a central island of vision with or without a temporal island or vice versa. Eyes with a visual acuity of 3/200 or less at the inception of treatment were excluded from this study because perimetry could not be done with sufficient accuracy.

The prevailing tension range was estimated from the recorded tensions on the patient's glaucoma clinic record. These tensions had been determined with Schiøtz tonometers, Schiøtz's conversion table of 1924 being used with J. Friedenwald's corrections for average ocular rigidity.[4] These tonometrics had been done between the hours of 10 a. m. and 2 p. m. and, in most instances, frequently enough to establish the patient's prevailing tension range, since the physician in charge of the glaucoma clinic was just as profoundly interested in this factor as we were. To what extent the patient's tension at other times of the day may have deviated from this prevailing tension range will be discussed later

---

[1] Fox, S. A.: Am. J. Ophth. **26:** 31, 1943.

[2] Barkan, O.: Am. J. Ophth. **21:** 1099, 1938.

[3] Gjessing, H. G. A.: Acta ophth. **5:** 149, 1927.

Four tension ranges were distinguished:

Range 1 ·	(hypotony)	From immeasurably low to 15 mm. Hg.
Range 2	(normal)	From 15 to 27 mm. Hg.
Range 3	(moderately elevated)	From 27 to 35 mm. Hg.
Range 4	(high)	From 35 mm. up

With regard to the course of the glaucomatous changes in the optic nerve there existed three possibilities: the disease might remain stationary, it might be progressive (further loss of visual field), or regressive (gain of visual field) The last possibility, that is, the reversible field changes associated with short episodes of elevated intraocular pressure and the slight improvements seen occasionally in chronic glaucomas after normalization of tension, have not been considered in this paper. Thus, there remained only the two possibilities of further progression or no further loss. In analyzing the changes in the visual field after surgical procedures the following types of further loss of visual field could be distinguished: (1) loss of visual field due to operative complications, such as traumatic cataract, intraocular or retinal hemorrhages, postoperative iridocyclitis; (2) loss of visual field directly following uncomplicated operations and reaching a standstill within two months after the operation; (3) loss of visual field due to diseases other than and unrelated to glaucoma (vascular or senile retinal or choroidal diseases, senile cataract); (4) gradual loss of visual field starting four to six months postoperatively and continuing from there in the manner generally thought to be typical of glaucoma.

In eyes treated with miotics the following types of further loss of visual field could be distinguished: (1) loss of visual field due to diseases other than and unrelated to glaucoma, and (2) gradual loss of visual field characteristic of and attributable to elevation of intraocular pressure or undetected phases thereof.

Only loss of visual field of type 4 in the surgically treated and of type 2 in the conservatively treated patients was considered to be truly glaucomatous and indicative of progression of the glaucomatous involvement of the optic nerve. Only in those cases in which on at least three occasions (during the five year period of observation) unquestionable further loss of field was recorded was the disease classified as being progressive. To qualify as unquestionable the loss of field had to be definite as compared to the immediately preceding test and had to be confirmed by all succeeding tests. In most of the progressive cases, unfortunately, unquestionable loss as compared with the immediately preceding test was recorded more than three times during the five year period.

In the majority of cases this further loss of field was attributable to continued elevation of intraocular pressure. There was, however, a goodly number of eyes with progressive course of the disease in the presence of normalized intraocular pressure. The possibility of undetected phases of elevated pressure in these cases will be discussed later.

If, during the five year period, such unquestionable loss was recorded less than three times the case was considered as stationary. Needless to say, in the stationary group were included those cases in which no further loss of field occurred during the five year period.

The final step in the classification was the distinction between narrow angle and wide angle glaucomas. This distinction was made on the basis of the gonioscopic and clinical observations and in accordance with the procedure outline in a previous publication.[5] The distinction between the two types could not always be made with absolute certainty. In this report there is a possibility of a few wide angle glaucomas having been mislabeled as narrow angle glaucomas. However, the conclusions which we have drawn could not have been significantly affected by such errors in classification.

The observation period of five years was chosen in preference to any shorter period because of its obvious value in demonstrating the truly stationary course of the disease after normalization of the ocular tension In the cases in whom the disease progressed despite normalization of tension a shorter period was sufficient to demonstrate this phenomenon convincingly.

RESULTS

This report is based on 225 eyes with wide angle and 100 eyes with narrow angle glaucoma. We believe that the proportion of 225 to 100 does not express the true incidence of the two types in an unselected population. We would estimate that 25 per cent or less of all so-called primary glaucomas are of the narrow angle type. The reason why this narrow angle type is found more frequently in a group of glaucomas followed for five years is its greater responsiveness to the ordinary methods of treatment as compared with the wide angle type. As a group, the patients with the narrow angle type are better satisfied, happier, more stable and less apt to seek help elsewhere. The latter is a characteristic and understandable reaction of the patient with the wide angle type who has been operated on unsuccessfully two or three times and has been advised to submit to more surgical treatment.

Table 1 shows the distribution of the material according to stage of the disease at the patient's first visit to the infirmary, as well as the over-all effect of the treatment on the prevailing tension range.

As a group, the patients with narrow angle glaucoma presented themselves at an earlier stage of the disease than the patients with wide angle glaucoma. The acuteness of the symptoms of narrow angle glaucoma in its dramatic as well as in its milder forms induces the patient to seek medical care at an early stage of the disease, in contradistinction to the fundamentally chronic wide angle glaucoma of which most patients do not become aware until a considerable portion of visual field has been lost. The relative frequencies of the three stages at the first visit to the clinic would not have been appreciably altered by listing patients instead of individual eyes.

Table 1 also shows that normalization of tension is accomplished in a considerably and significantly larger percentage of narrow angle glaucomas (84 to 88 per cent) than of wide angle glaucomas (52 to 58 per cent).

To evaluate the figures of columns 5, 6, 7 and 8 of table 1 properly, a little more must be said about the procedure followed in classifying the material.

---

[4] Friedenwald, J. S.: Am. J. Ophth. 20: 985, 1937.

[5] Kronfeld, P. C.: Gonioscopic Correlates of Responsiveness to Miotics, Arch. Ophth. 32: 447 (Dec.) 1944.

To qualify for a place in one of these four columns the particular eye had to fulfil the respective requirement, that is, be normalized or not normalized by either surgical treatment or miotics during the whole five year period. Each eye was listed but once, namely as (*a*) normalized by surgical treatment if miotics had been tried unsuccessfully and surgical treatment alone, without the help of miotics, had succeeded in normalizing the tension; (*b*) normalized by miotics if the latter had normalized the tension without surgical treatment having been tried or after unsuccessful surgical treatment; (*c*) not normalized by surgical treatment if both surgical treatment and miotics, separately and together, had failed to normalize the tension, and (*d*) not normalized by miotics if the latter had failed to normalize the tension without surgical treatment ever having been tried.

In principle, surgical treatment was advised only after miotics had been tried for a sufficiently long period and had failed to normalize the ocular tension. Naturally, surgical advice was given more strongly and taken more readily if further loss of visual field had occurred during the period of conservative treatment or if the glaucoma was of the acute type.

Table 1, therefore, implies, though it does not state so explicitly, that miotics had failed not only in the eyes listed in column 8 but also in the eyes listed under 5 and 7. Thus, in the wide angle glaucomas of stage 1, the ratio of success to failure of miotics was 27:88 (0.31) and in the narrow angle glaucomas of the same stage 35:40 (0.88). We are convinced that the miotics are much more effective as tension-lowering agents in narrow than in wide angle glaucomas, but because of the fundamental difference in the course of the two types of glaucomas we doubt that the difference is accurately expressed in the two ratios (0.8 against 0.31) The dramatic course of narrow angle glaucoma, on the one hand, is apt to "scare" patient and surgeon into early operations[6] which might have been made unnecessary by application of a stronger miotic. The chronic course of wide angle glaucoma, on the other hand, is conducive to an attitude of procrastination on the part of the physician, as well as of the patient, especially if there is no rapidly progressive loss of field. That explains why 32 cases of wide angle galucoma (stage 1) were permitted to remain with tension not normalized for five years. Failure of surgical therapy in the patient's other eye may have been additional evidence in favor of conservative therapy. In narrow angle glaucoma, the state of nonnormalized tension is usually painful and always associated with rapid loss of visual field, so that few patients persisted in their refusal of surgical treatment for five years. These characteristics of the two types of glaucoma make the results of conservative treatment not strictly comparable, but the greater efficacy of the miotics in the narrow angle group is obvious.

With regard to the results of surgical treatment, the comparison of the two groups is probably "fairer." Again, strikingly better results are recorded in narrow angle than in wide angle glaucomas, the ratio of success to failure being 31:6 and 34:22 respectively. The large majority of the operations in narrow angle glaucoma naturally were iridectomies.

The reason for this difference in responsiveness to therapy between the two types of primary glaucoma, we believe, lies in the difference in mechanism. There is good evidence to the effect that in narrow angle glaucoma the trabecula-canal of Schlemm mechanism is and remains normal until the trabecular spaces are completely closed off from the anterior chamber by goniosynechiae. The aim of the treatment is to keep the trabeculae accessible to the aqueous, which is easily accomplished with miotics or an iridectomy. In most wide angle glaucomas, on the other hand, the disturbance is probably due to impaired function of the trabecula-canal of Schlemm mechanism itself, and therefore much more deeply rooted than in narrow angle glaucoma. Failure of the miotics calls for an operation of the filtering type, the success of which is still, to a considerable degree, dependent on factors not completely understood and not under the control of the operator. A very different situation prevails with regard to iridectomy in cases of narrow angle glaucoma, in which the surgeon has under his control almost all the factors that determine the outcome of the operation. In view of the fundamental differences between the two types of so-called primary glaucoma, they will from here on be discussed separately.

So far we have described the composition of the material at the inception of therapy and the over-all effect of the treatment on the prevailing range of tension. We are now turning to the description of the course of the disease as related to or influenced by the prevailing tension range.

TABLE 1.—*Distribution of the Material (Eyes) According to Type of Glaucoma and Stage of Disease at Inception of Treatment; Effect of Treatment on Tension*

1	2	3	4	5	6	7	8
			Tension Normalized			Tension Not Normalized	
Type of Glaucoma	Stage of Disease	Number of Eyes	Total Number	By Surgical Treatment	By Miotics	By Surgical Treatment	By Miotics
Wide angle, 225 eyes................	1	115 (51%)	61 (53%)	34	27	22	32
	2	56 (25%)	32 (58%)	26	6	16	8
	3	54 (24%)	28 (52%)	28	0	18	8
Narrow angle, 100 eyes..............	1	75 (75%)	66 (88%)	31	35	6	3
	2 and 3	25 (25%)	21 (84%)	19	2	4	0

WIDE ANGLE GLAUCOMAS

The course of the glaucomatous involvement of the optic nerve under the influence of treatment intended to lower the tension is shown in three graphs (figs. 1, 2 and 3) corresponding to the three stages of the disease defined previously. The plan underlying the graphs is that of a coordinate system, with the tension range recorded on the ordinate against time (five years) on the abscissa. The horizontal line across the center of the graphs marks the 27 mm. level. Circular areas are used to indicate the number of eyes that exhibited the phenomenon to be illustrated, that is, the course of the glaucomatous involvement of the optic nerve. White is used to indicate the stationary and dark gray to black, the progressive course. Shaded circles indicate the "uncertain" state of the eyes at the inception of therapy. From these shaded circles, arrows, implying tension-lowering treatment, lead to the partly white, gray and black circles illustrating the phenomena of stationary or progressive course. The size of the white, gray or black sectors expresses the relative frequency with which these phenomena occurred within the respective group of eyes.

---

[6] We practice and advocate early operations for acute narrow angle glaucoma because of (1) the high percentage of successes of and the small risk entailed in iridectomies and (2) the frequent necessity to operate under less favorable conditions later on.

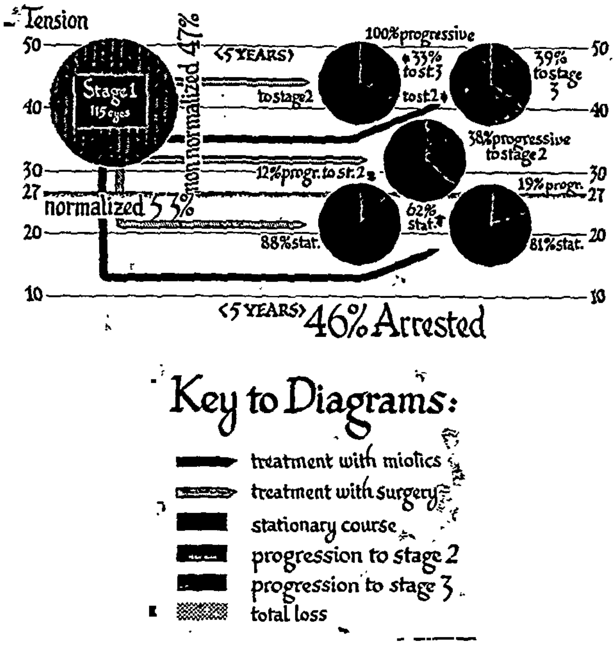

Fig. 1.—Wide angle glaucomas, stage 1.

Stage 1.—Graph 1 illustrates the relative frequency with which the stationary or progressive course occurred after normalization or nonnormalization of tension in eyes representing, at the inception of treatment, stage 1 of the disease. It was gratifying to find that after normalization of tension the course of the glaucomatous involvement of the optic nerve became stationary in 88 per cent of the surgically treated eyes and in 81 per cent of the conservatively treated eyes. Thus, the overwhelming majority of eyes of stage 1 showed favorable response to normalization of tension. The few eyes in which the disease continued to progress despite surgical normalization were borderline cases in that the field defect at the inception of treatment was almost of the magnitude characteristic of stage 2.

In every one of the nonnormalized eyes of stage 1 at the inception of treatment the disease progressed during the five year period; approximately two thirds of the eyes reached and remained within stage 2 while the remaining one third went on to stage 3. It is not clear from our material whether in the eyes with higher prevailing tension range the disease progressed further or faster than in the eyes with moderately elevated tensions. As was to be expected, good central visual acuity was maintained in 83 per cent of the nonnormalized eyes and became impaired as the result of glaucoma in only 17 per cent.

In a number of eyes the disease was consistently borderline in the sense that the treatment effected lowering of the tension to the range from 24 to 35 mm., with an average of between 27 and 30. The disease remained stationary in 62 per cent of these eyes and progressed in the remaining 38 per cent.

In summary, the eyes of stage 1 behaved as one would expect glaucomatous eyes to behave, the course of the disease of the optic nerve showing a close dependence on the prevailing tension range. Apparent independence occurred in only a few eyes in which the disease progressed despite normalization of tension. As stated before, the surgically treated eyes of this group were bordering on stage 2 at the beginning of treatment. Those treated conservatively do not prove independence with certainty, since miotics do not afford the same degree of protection against elevated tension "twenty-four hours a day" as surgical treatment. Thus, it may be said that in eyes with stage 1 of wide angle glaucoma independence of the glaucomatous involvement of the optic nerve from the prevailing tension range is rare enough to be considered an exception.

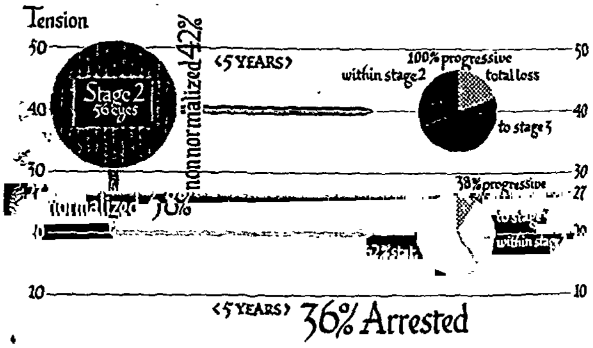

Fig. 2.—Wide angle glaucomas, stage 2.

Stage 2.—The striking feature with respect to eyes of stage 2 at the inception of treatment is the large (38) percentage of further progression of the glaucomatous involvement of the optic nerve in the group in which tension was normalized surgically. No comparable group treated with miotics was available for the obvious reason that in the face of further progression after normalization of tension by miotics the physician in charge naturally suspected the conservative treatment to be somewhat inadequate and resorted to surgical treatment. The progression proceeded in the stage 2 eyes in which the tension was normalized and in those in which it was not at about the same rate: About 30 per cent of the eyes in each group remained in stage 2, about 50 per cent of the eyes advanced to stage 3, and the remaining 20 per cent became entirely blind. Another characteristic feature of this stage was the frequent association of initially poor central visual acuity with marked to total further loss of central acuity and field on the one hand, and the frequent association

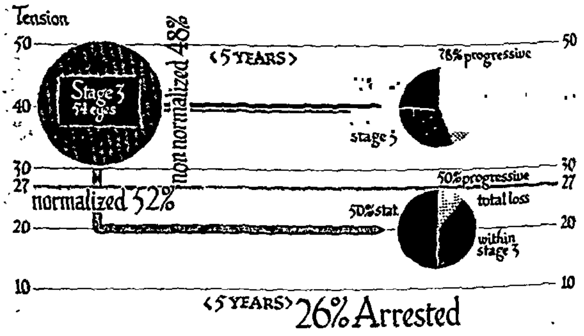

Fig. 3.—Wide angle glaucomas, stage 3.

of good initial visual acuity with a stationary course of the disease on the other hand.

Stage 3.—Eyes that were in stage 3 initially showed a behavior similar to that of eyes of stage 2. The percentage of further progression in tension-normalized eyes was still greater than in eyes of stage 2 (50 per cent against 38 per cent). The same relationship between initial central acuity and course of the disease prevailed in eyes of both stages. Twenty-three per cent of the group in which the tension was not normalized showed the remarkable feature of endurance of high tension ranges without further loss. These eyes showed initially small central or chiefly temporal field islands and represent the only examples of field remnants in primary glaucomas that sustained high ocular tension for five years without any loss.

NARROW ANGLE GLAUCOMAS

The course of narrow angle glaucoma under the influence of treatment intended to lower the ocular tension is shown in graphs 4 and 5. Under conditions of nonnormalization the glaucomatous disease progressed rapidly to total blindness. Under conditions of normalization the disease remained stationary during the five year and, in many instances, longer periods in approximately 90 per cent of all tension-normalized eyes, irrespective of the stage at which the normalization took place. Further progression occurred in less than 10 per cent of the normalized eyes of stage 1 and in a little more than 10 per cent of the normalized eye of stages 2 and 3, which is a strikingly low percentage compared to wide angle glaucomas.

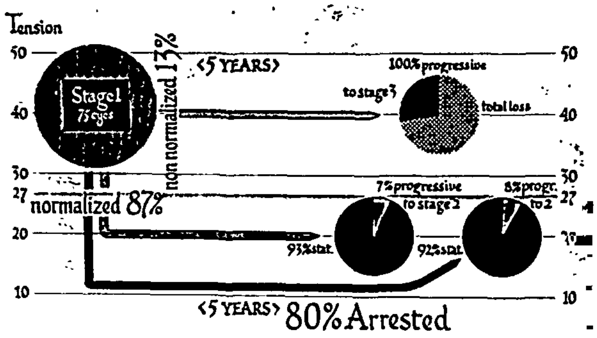

Fig. 4.—Narrow angle glaucomas, stage 1.

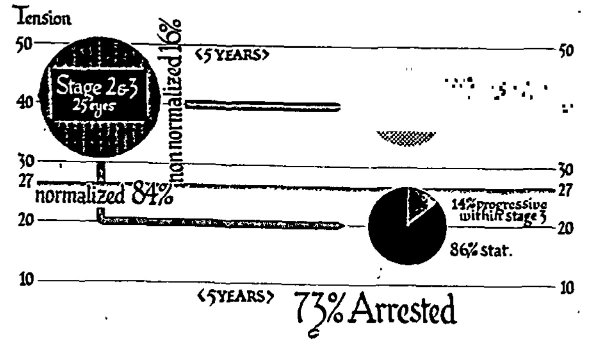

Fig. 5.—Narrow angle glaucomas, stages 2 and 3.

COMMENT

This survey has brought to the fore two phenomena which, while not new in any sense of the word, are remarkable in that they suggest independence of the course of the glaucomatous involvement of the optic nerve from the prevailing tension range.

The first phenomenon, the further progression of the glaucomatous involvement of the optic nerve after normalization of tension, occurred in 35 eyes with wide angle and in 8 eyes with narrow angle glaucoma. The size of this group permits some general conclusion.

This phenomenon almost invariably became manifest toward the end of the first year of normalized tension. Thus, it did not require a period of observation of five years to establish with certainty the fact of further progression. The progression of the glaucomatous involvement of the optic nerve after normalization of tension takes the same course as the "true" glaucomatous disease as far as can be judged from perimetric and visual acuity findings. Despite the normalization of tension, the deterioration of the visual field continues in accordance with the pattern so well established for the glaucomas and so well described by Traquair [7] and Lauber.[8]

Another obvious characteristic of the phenomenon of further progression after normalization of tension is its more frequent occurrence in the more advanced stages of the wide angle glaucomas. The relative frequencies of 12, 38 and 50 per cent, respectively, of further progression for the three stages of our material of wide angle glaucomas agree closely with the observations of A. B. Reese,[9] presented before this society in 1939, and of J. W. Burke,[10] presented before the American Ophthalmological Society in the same year. In the words of the latter author, "the fields are best retained in those cases in which little damage has been suffered before operation."

In our series the narrow angle glaucomas differed significantly from the wide angle glaucomas in that further progression after normalization of tension was a less common phenomenon and independent of the stage of the disease at the inception of treatment. Further analysis showed that in the far advanced narrow angle glaucomas, in which the disease remained stationary after normalization of tension, the disks showed the characteristic picture of atrophy of the postneuritic type without excavation. In these cases one or a few severe acute attacks, rather than frequent mild attacks, had caused the loss of visual function. In the few narrow angle glaucomas that showed further progression, typical deep glaucomatous excavations were present, just as in the cases of advanced wide angle glaucoma. Further progression after normalization thus appeared to be associated with deeply excavated disks and nonprogression with flat disks.

Special attention was paid to a possible relationship between further progression of the glaucomatous involvement of the optic nerve and the prevailing tension within the normal range. The problem consisted of three parts, namely:

1. What evidence is there that eyes with wide angle glaucoma may have such a low ocular rigidity as to give normal tonometric readings in the presence of elevated intraocular pressure?

2. What evidence is there that eyes which, on frequent tonometries during morning hours, consistently

gave readings below 27 mm. of mercury actually were tension normalized, that is, at all other times of the day would have given tonometric readings below 27?

3. What evidence is there that tension-normalized eyes may have such a low tension tolerance (H. S. Gradle[11]) as to be harmed by the normal tension range?

With regard to point 1, J. Friedenwald and D. Harrington (personal communication) have found that primary glaucomas possess average ocular rigidity. Thus, it is unlikely that in our group of eyes showing further progression after normalization of tension, a state of elevated intraocular pressure was masked by unusually low ocular rigidity.

With regard to point 2, the task was to look for a residuum of the glaucomatous elevation of intraocular pressure or to simulate it by means of provocative tests. The former was done by observing the diurnal variations in ocular tension either in the hospital or under conditions of normal unrestricted life. On patients with filtering operative scars of either the transconjunctival or the subconjunctival filtration type and routine morning tensions below 27 mm., diurnal variations of the ocular tension are difficult to demonstrate. These eyes are characterized by such a high degree of constancy of the tonometric reading that an occasional deviating reading is more apt to be due to a clinical experimental error than to an actually deviating tension.

Of the usual provocative tests, the drinking test of Marx appeared to be best suited for wide angle glaucomas (Kronfeld, McGarry and Smith[12]). In a study of the response of eyes with functioning operative filtering scars to the drinking test, J. S. Haas of this institution (in an article to be published) found fluctuations of the ocular tension of lesser magnitude than in normal eyes with the same initial tension. By these criteria, the functioning filtering scar in eyes with consistent pressure readings under 27 mm. of mercury seems to work as a safety valve of at least the same capacity as the normal trabecula-canal of Schlemm apparatus. This cannot be said for miotic-controlled eyes in which the drinking test frequently causes a rise as great as or greater than in a normal eye. Thus, in all miotic-normalized eyes in which there is further progression of the glaucomatous involvement of the optic nerve in the face of apparent normalization of tension, there is a definite possibility of insufficient normalization.

With regard to point 3 the eyes with stationary disease and those with further progressive disease in which the tension has been normalized surgically have been grouped (table 2) according to the prevailing tension range, which is either hypotony (below 15, range 1) low (range 1-2 with an average of 15) or normal (range 2 with variations between 18 and 27), and we found essentially the same relative frequencies. In other words, in the eyes with stationary disease and in those with further progressive disease, hypotony, intermediate and normal tension ranges occur with equal relative frequency. If the mechanism of further progression were due to a greater sensitivity to or to a lesser tolerance of ocular tension, one would expect the higher tension ranges (range 2) to occur more frequently in the eyes with progressive disease than in those with nonprogressive disease. This, however, was not the case. The equally frequent occurrence of the three normal tension ranges in the eyes with progressive and in those with nonprogressive disease speaks strongly for independence of the phenomenon of further progression of the prevailing tension. For the same reason, the prevailing tension range is unlikely to be an important factor in the mechanism of the further progression after normalization of tension. These observations fail to lend support to the concept of tension tolerance.

TABLE 2.—*Relative Frequency of the Three Normal Tension Ranges After Surgical Normalization in Stationary and Further Progressive Primary Glaucomas*

Course of Disease	Tension Range		
	1	1 to 2	2
Stationary	26%	15%	59%
Progressive	30%	22%	48%

The type of operation that produced the normalization did not seem to be an important factor either, since the three main types of operation, corneosclerectomy, iridencleisis and cyclodialysis, are represented in about the same frequency in the surgically normalized eyes with further progressive disease.

Other than the deep complete glaucomatous excavation, these progressively diseased eyes did not exhibit any ophthalmoscopic characteristics. They did not show vascular changes of the retinal or ciliary system with any greater frequency or severity than the eyes with nonprogressive disease.

A definite and consistent relationship was found between the course of the disease after normalization of tension and the visual acuity related to the glaucoma and prevailing at the time the normalization became effective. By visual acuity related to glaucoma, we mean the acuity affected or unaffected by the glaucomatous involvement of the optic nerve and not by any other manifestations of glaucoma (opacities of the media) or coincidental diseases. Arbitrarily we chose the corrected acuity of 20/50 as the borderline between good or slightly impaired vision on the one hand and markedly impaired vision on the other hand. In many of the eyes with a corrected visual acuity of less than 20/50, the field defect could be shown to involve the very center of the field, in the form of a wedge scotoma such as described by Evans.[13] Table 3 shows the relative incidence of good and poor visual acuity in the surgically normalized eyes with stationary and progressive wide angle glaucoma of stages 2 and 3. There was a definite majority of eyes with good visual acuities in the stationary and of eyes with poor visual acuities in the progressive group. It appears that an eye with good visual acuity after normalization has become effective has about twice as good a chance of retaining its visual functions as an eye with poor acuity. By the same token, the possibility of further progression after normalization is twice as great in eyes with poor acuity as in eyes with good acuity.

TABLE 3.—*Relationship Between Course of Disease and Visual Acuity*

Course of Disease After Normalization	Corrected Visual Acuity	
	>20/50	<20/50
Stationary (100%)	73%	27%
Progressive (100%)	34%	66%

Heretofore, the term progression has been used to describe further loss of visual field irrespective of its location within the field. The relationship between visual acuity and incidence of further progression discussed in the foregoing suggests an exceptional position of the center of the visual field as far as progression of the glaucomatous involvement of the optic nerve is concerned. Further evidence along this line is obtained by determining the chances of survival, after normalization of tension, for specific portions of the visual field. Since further progression after normalization of tension takes the same course as "true" glaucoma, the paracentral portions of the upper nasal quadrant have the greatest and similar portions of the lower nasal quadrant next to the greatest specific susceptibilities to further progression. The incidence of further progression in eyes of stage 2 (graph 2) refers primarily to those paracentral nasal portions of the field. During the first and most of the second stage of glaucoma, the site of the glaucomatous loss of field keeps 5 to 10 degrees from the center of the field, so that the sparing of the latter is not remarkable.

When, during the late stages of glaucoma, the "battle" is brought right to the center of the field, the latter shows the remarkable power to survive which has been pointed out recently by E. V. L. Brown[14] and A. B. Reese.[9] Among 18 surgically normalized eyes of stage 3 with good acuity and field defects extending within 5 degrees of the center of the field, the central circular area of 2 to 3 degree radius survived in 15 and was damaged or lost in 3 eyes. The chances of survival of the center of the field may thus be said to be 83 per cent, a remarkably high percentage for eyes with such extensive field defects. These observations speak for a specific resistance of the very center of the visual field to the further progression of the glaucomatous involvement of the optic nerve after normalization of tension.

Analogous observations have been made under conditions of nonnormalization under which all portions of the visual field eventually fall victims to the disease with the exception only of the very center and, occasionally, the temporal crescent. Among 12 eyes of stage 3 in which the tension had not been normalized the center was preserved in 9 and lost or damaged in the remaining 3. That would mean that the chances of survival of the center of the field under conditions of nonnormalization are 75 per cent, not appreciably worse than under conditions of normalization. The number of eyes on which these observations were made is too small to establish quantitatively the degree of resistance of the center of the field under conditions of nonnormalization of tension: It seems highly probable, however, that the chances of survival of the center of the field are not much poorer under nonnormalization than under normalization of tension.

The objection may be raised that in eyes with very small central field islands further progression of the glaucomatous involvement of the optic nerve is difficult to recognize. Since all these eyes had good central acuities, we feel that the consistency of the perimetric findings obtained by the Bjerrum technic and the consistency of the central acuity measurements make it highly probable that no portion of the small central island became lost during the five year period. We therefore interpret the apparent survival of small central islands as a phenomenon of specific resistance of the corresponding portion of the optic nerve rather than as an immeasurably slow loss. This phenomenon of specific resistance, just as the phenomenon of further progression after normalization, has long been known to ophthalmologists.[9] We are unable to furnish any new clues to the possible mechanism of either phenomenon. Our estimates of the chances for survival of the various portions of the field (graph 6) in the three stages of the disease may prove helpful in the management of glaucomas.

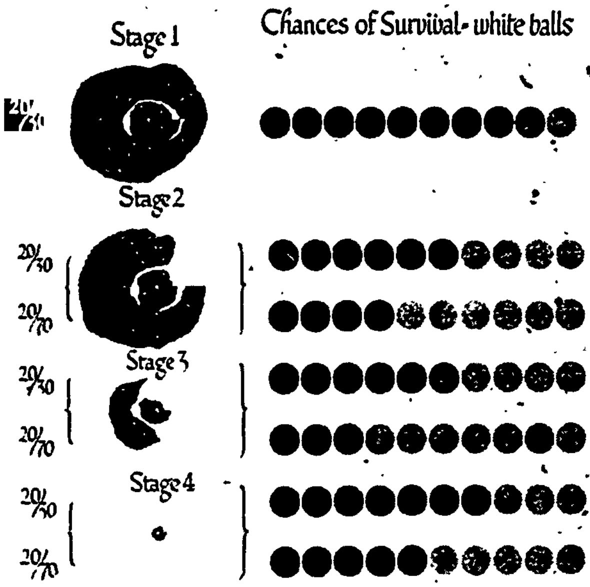

Fig. 6.—Chances of maintaining the visual status quo by normalization of tension (wide angle glaucomas).

In making the choice between surgical and conservative treatment, the physician will naturally have to consider the surgical risk, which depends on factors other than the type of eye operated and the type of operation performed, so that the figures calculated for this institution would not apply to any other institution or private practice. Thus, the surgical risk is a factor that every surgeon will have to estimate for himself.

The frequent occurrence of further eccentric field deterioration after normalization and of survival of central field islands despite nonnormalization may make the treatment of glaucoma appear more discouraging and complicated than it actually is. For while it is true that in wide angle glaucomas of stage 2 or 3 in a goodly percentage of surgically normalized eyes the disease progresses at about the same rate as in eyes in which the tension has not been normalized, we must constantly remind ourselves that in at least 50 per cent of the surgically normalized eyes the course of the disease has been radically improved over what it would have been had the tension not been normalized. It is true that in many of these cases the amount of peripheral field preserved by treatment is not enough to rehabilitate the patient economically. Still, the preservation of even such small rests of visual function must be considered as very worth while objectively as well as subjectively. Surveys such as this one bring out clearly the two main aims in the field of glaucoma: (1) the early recognition of wide angle glaucoma in the entire population and (2) the recognition of the factors that determine the outcome of filtering operations.

---

[14] Brown, E. V. L.: Am. J. Ophth. 20: 1250, 1937.

Other aspects of the course of glaucoma, such as the formation of opacities in the lens in relation to glaucoma or glaucoma operations, the vascular diseases of the retinal and ciliary system secondary to glaucoma, changes in the capacity of filtering scars, the phenomena of direct and indirect operative loss of visual function will be dealt with in a later publication.

SUMMARY

The purpose of this survey was to determine on a representative group of cases the course of so-called primary glaucoma under the influence of treatment intended to lower the ocular tension. Because of gross differences in the response to such treatment, it was found advisable to separate the wide angle from the narrow angle glaucomas. The treatment accomplished normalization, seminormalization or nonnormalization of ocular tension. Only eyes that remained in that respective state for at least five years were included in this study. The course of the disease, whether stationary or progressive after normalization of tension, showed a strong dependence on the stage of the disease present when the normalization became effective. In eyes with early stages of wide angle glaucoma the course of the disease was closely dependent on the prevailing tension range, normalization of tension resulting in a high percentage of arrest of the disease ("cures"). Seminormalization of tension at an average level around 28 mm. was sufficient to preserve the existing visual function in two thirds of eyes with early wide angle glaucoma. Later stages of glaucoma, as had been shown recently by A. B. Reese and J. W. Burke, showed a strong tendency toward further progression of the disease despite normalization of tension. The very center of the visual field seemed to exhibit a specific resistance to the glaucomatous disease. The chances of survival after normalization of tension were estimated for the respective stages of the disease. It is hoped that these estimates will prove of value to the ophthalmologist.

ABSTRACT OF DISCUSSION

Dr. Algernon B. Reese, New York: Drs. Kronfeld and McGarry have divided their cases into deep and shallow angle glaucoma, and their analysis implicates the deep angle glaucoma as the greater offender in this phenomenon of progressive field changes in the presence of normal tension. Their figures are convincing. In wide angle glaucoma only 15 per cent of Group 1 cases progressed, and these were borderline group 2 cases, whereas 38 and 50 per cent respectively progressed in the cases of groups 2 and 3, and the progression was at about the same rate in eyes in which the tension was normalized and those in which the tension was not normalized. This is in contrast to narrow angle glaucoma, in which only 10 per cent showed progressive field changes with normalized tension irrespective of the stage of the disease. The screening of the cases from which they have made their deductions seems to me beyond criticism. The division of primary glaucoma into wide angle and shallow angle types is the soundest basic classification. The narrow angle glaucoma is due to some transitory functional factor back of the iris which pushes the root of the iris forward against the angle, while deep angle glaucoma is due to organic obstruction in the trabecular area. Histologic evidence indicates that this trabecular obstruction can be due to the secretion of a cuticular product of the endothelial cells lining the interstices of the trabecula (Reese, A. B.: Deep-Chamber Glaucoma Due to the Formation of a Cuticular Product in the Filtration Angle, *Am. J. Ophth* **27:**1193, 1944). The lamina vitrea is also a cuticular product, and it may be that deep angle glaucoma is characterized by an overproduction of the cuticular product of the eye. This might throw some light on the most interesting finding of Drs. Kronfeld and McGarry regarding the correlation in deep angle glaucoma between defective central vision and the progression of the field changes. They deduced that an eye with good visual acuity after normalization of tension has about twice as good a chance of retaining its visual function as has an eye with poor acuity. This relationship might be due to the fact that the same process which fills the interstices of the trabecula also causes a thickening of the lamina vitrea. This results in decrease in the permeability of the lamina vitrea sufficient to impair the nutrition of the retina, especially in the macular region where it is so dependent on the choroid for nourishment. The essayists have supported their main thesis with convincing facts. Almost every phase of the analysis so ably carried out by Drs. Kronfeld and McGarry points to the importance of early recognition and treatment of primary glaucoma. This objective is most difficult to achieve in the deep angle type which is the type in which it is most important.

Dr. M. Elliott Randolph, Baltimore: Dr. Kronfeld states that the type of operation producing the normalization did not seem to be a factor. This observation is in partial agreement with the result of a series of glaucoma cases published a few years ago (1941) from the Glaucoma Clinic of the Wilmer Institute. This was a statistical study, essentially a comparison between the end results of trephine and iris inclusion operations, in a carefully selected group of cases. It was found in late cases which Dr. Kronfeld would consider stage 3 and late stage 2, whether wide or narrow angle, the results were identically poor with either operation. In stage 1 of wide angle glaucoma, the trephine operation was successful in 85.5 per cent, and the iris inclusion in 80 per cent, not a too striking difference. However —and this is the point which I would like to stress—in stage 1 of narrow angle glaucoma, the trephine operation was successful in but 62.5 per cent, whereas the iris inclusion was successful in 88.2 per cent. It has, therefore, been our custom, with rare exception, never to do a trephine operation except in wide angle glaucoma. The various theories as to why there should be further loss of field and vision in "tension-normalized" eyes are fascinating. However, it would seem that such an eye severely damaged by long standing pressure can scarcely be called "tension normalized" by our standards. It is obviously not fulfilling the definition of normal as being that degree of pressure which the tissues of the eye are able to withstand without impairment of function. From the paper which we have just heard, it would seem that in tension-normalized eyes we can now predict with better accuracy statistically just what cases will be controlled and what cases will progress. In discussing Burke's paper referred to by the essayists, the late Dr. Gifford suggested that further progression was somewhat rarer in those cases in which the tension was low. This is true in the group which we studied. However, other than desperately using drops of all types—"furmethide" (furfuryl trimethylammonium iodide), "doryl" (carbaminoyl choline) "mecholyl bromide" (acetyl-beta-methylcholine bromide) and neostigmine and DFP (di-isopropyl fluorophosphate)—we rarely do anything else if the tension hovers around 25 to 30. In spite of the fact that we have assurance that some of these patients do not eventually go blind, it would seem that further surgical treatment is indicated. This excellent paper is great credit not only to the authors (Dr. Kronfeld and Dr. McGarry) but also to what is obviously a highly efficient glaucoma clinic from which these cases originated.

Dr. Louis Lehrfeld, Philadelphia: Like most statistical studies, there are shortcomings. Some time ago I was a statistician. I had been computing the mortality among Italians. I found in one town that the mortality was 50 per cent. In looking up the records, I found there were only 2 Italians, and 1 died. So in dealing with small numbers, one makes great mistakes. Of course, Dr. Kronfeld has a large series of cases, but when he compares a small series of 52, half of which are normal eyes, the 26 gives a percentage number that is greater than the original figure. I, too, had experience in statistical compilations. In the year 1936 I published a report of a survey on glaucoma in Wills' Hospital over a period of ten years, 1926-1935, in which I reported 1,875 cases of glaucoma that were observed over a period of ten years. In that series it was found that 27 per cent of the primary glaucomas were of the congestive type (what I would like to call the wet types of glaucoma) and 73 per cent were noncongestive or dry. Of course there are some cases that are neither in the dry stage nor the wet stage; they are partially dry and partially wet. For statistical purposes, I like to call the acute and chronic congestive glaucoma the wet type and the wide angle or the chronic glaucoma the dry type. The point of interest in Dr Kronfeld's paper is the fact he mentions that cases of glaucoma are treated medically and surgically Too many of us have the impression —and the textbooks sometimes mention it—that glaucoma is a surgical disease whenever and wherever one sees it. Dr. Kronfeld did not make such mention in his statistics. I am firmly convinced that glaucoma is not a disease to be treated by surgery alone. Furthermore, when we use the term medical and surgical treatment, we should not feel for one moment that the term "medical" is a definite entity or that the term "surgery" is a definite entity or quantity. I am still a little uncertain what Dr. Kronfeld means when he speaks of normalizing glaucomatous eyes. I can conceive of a diabetic patient being normalized, but that patient is still diabetic. I can conceive of a patient having a general hypertension being normalized, and still that patient is a hypertensive patient. In glaucoma, patients having normal tension still have the causative factors which produced the glaucoma. I have come to the conclusion that we are all operating at the wrong place for glaucoma. We are operating the corneosceral junction. We all know that that is where the obstruction occurs. It is my belief that the point of drainage should be further backward in the region of the pars planum of the ciliary, which I call the silent area of the eye.

Dr. T. D. Allen, Chicago: We who have been associated more or less intimately with the work of the Glaucoma Clinic at the Illinois Eye and Ear Infirmary for the past several years have been increasingly interested in the statistics and analyses that Dr. Kronfeld and his associates in that clinic have given us. The continuous study has entailed an enormous amount of work not only in the examinations but also in the grouping of records, so that scientific conclusions will become available for teaching purposes. The authors are to be congratulated for the graphic manner in which these conclusions have been portrayed, and I hope you will not only see his exhibit, but read the paper carefully. Some of us probably have not related the prognostic value of the classification wide angle and narrow angle glaucoma. We have known for years that the earlier the treatment is started, the better the prognosis is. We frequently tell our own patients that it is easier to stop a bobsled on the top of the hill than part way down, but the fact that we have almost twice as good a prognosis in narrow angle glaucomas as in wide angle glaucomas, no matter what treatment is given, may be the stimulus that some young man in this audience needs to improve on our concepts of the disorder, and, consequently, its management. On the other hand, it is interesting to learn by these statistics that our conception that some "tension-normalized" eyes proceed on their way to blindness means that ocular hypertension is apparently not the only etiologic factor in the disorder, although it may be the most important. We know that a patient with an emotionally disturbed personality is more difficult to control. Can there be a relationship between the causes of the emotional instability and this unknown etiologic factor? One point in the paper which might be further emphasized is the sparing of the area of central fixation in many eyes the fields of which have otherwise been destroyed. We have so often heard it said, "Don't operate if the peripheral field is gone or you will surely destroy the central field." Of the authors' 18 cases of surgically "tension-normalized" eyes in stage 3 when first seen, 15 continued to have good central vision, and in only 3 did this field succumb. It will be interesting to learn what another five or ten years will do to these patients as compared to the 9 or 12 patients who have preserved the central field, although the tension was not normalized. Five years' close observation of a great number of patients is a tremendous task, but, after all, five years is not long to a patient in middle life if he has chronic simple glaucoma.

Dr. Peter C. Kronfeld, Chicago: I am deeply indebted to the discussers for having shed so much more light on the material that we have presented here. Dr. Reese's theory that the obstruction of the trabeculum in the anterior portion of the eye may be paralleled by a similar degenerative process involving the lamina vitrea in the posterior segment is very interesting. I do not believe that Dr. McGarry and I are completely satisfied with the pure nerve fiber concept of visual defects in glaucoma. Especially since seeing the exhibit by Drs. Posner and Schlossman, we are more inclined to think in terms of a combined, nerve fiber and vascular concept of the field destruction in glaucoma. With regard to Dr. Randolph's comment, which I appreciate very much, we said little in our paper about the surgical means which were used to bring about the state of normalization. We did say, however, that the phenomenon of further progression after normalization occurred with more or less the same frequency after all three main types of surgical treatment, that is, corneosclerectomy, iridencleisis or cyclodialysis. Therefore, we felt that the type of operation had nothing to do with the phenomenon of further progression. Since Dr. Randolph mentioned the glaucoma survey from the Wilmer Institute, I would like to say that our own observations also indicate that in the eyes with very narrow, very crowded angles, the operation which is generally called iridencleisis, definitely fares better than the operations which come under the general heading of corneosclerectomy. I believe all corneosclerectomies need more "elbow room" than the operations that we call iridencleises. In other words, in crowded quarters the iridencleisis has a better chance to succeed than any form of corneosclerectomy. I speak of corneosclerectomy as a general term for any form of excision of parts of the fibrous coat in the anterior segment of the eye, the trephine being just one form of corneosclerectomy. I appreciate Dr. Lehrfeld's remark. Perhaps we should have put the word normalized in quotes. In the paper we have clearly stated our criteria of normalization. We are well aware of the fact that in many respects our series was too small, and it is for that reason that in all our slides we showed the actual number of eyes that exhibited the particular phenomenon so as to prevent any conclusions based on too few cases. I thoroughly agree with Dr. Thomas Allen that the period of observation of ten years or fifteen years would throw more light on the problem than our period of five years. However, the phenomenon of further progression after normalization is very evident at the end of the first year.

HORMONAL TEST FOR FETAL DEATH IN DISTURBED PREGNANCY

BERNHARD ZONDEK, M.D.
FELIX SULMAN
and
RYVKA BLACK
Jerusalem Palestine

When a woman begins to bleed during the first months of pregnancy, great care must be exercised in order to save the pregnancy, particularly if the patient has been suffering from habitual abortion. It is often possible to tide such patients over the critical period after weeks of bed rest combined with hormone and other treatment, thereby saving the lives of children who would otherwise be lost. On the other hand, even when the same precautionary measures and methods of treatment are employed, we frequently encounter failures resulting in abortus after the patients have had to neglect their home responsibilities to no avail for weeks and to undergo a series of costly treatments. We have hitherto had no clinical method for establishing the important differential diagnosis whether pregnancy may or may not be maintained in any particular case. Can this be decided by means of a laboratory test?

Since the discovery of the pregnancy test we have been considering this question, basing our analysis on the premise that with the death of the fetus the first

---

From the Gynecologic-Obstetric Department of the Rothschild Hadassah University Hospital and the Hormone Research Laboratory organ to die is the placenta, the cessation of the hormonal function of which must be demonstrable. Since gonadotropin is produced in great quantities during the earliest stages of development of the ovum, whereas estrogen first appears at a much later period (three to four months of pregnancy), it is clear that the demonstration of gonadotropin, and particularly of a drop in the production and excretion of this hormone, comes under consideration for our test. In cases of habitual abortion or threatened abortion the most important decision from a clinical point of view must be taken during the first months of pregnancy.

During recent years we have studied the hyperemia effect of gonadotropin on the ovary of the infantile rat [1] with the view of using this as a pregnancy test, and we have found that the cessation of placental function may be established with reasonable certainty by the titration of the patient's urine for the presence of the hyperemia factor (hyperemia titration test). In this way we have obtained a clinically useful test for determining whether a pregnancy with a disturbed clinical course may or may not still be saved. We believe that with the aid of this test curettage may be avoided and that pregnancy may thus be maintained in spite of bleeding in certain cases which would hitherto have been considered hopeless, and that, on the other hand, long drawn out and costly treatment may be avoided in cases in which the fetus is already dead.

The following are the biologic bases of the test, which is naturally founded on the hormone pregnancy test (Aschheim-Zondek test)[2]: (1) explosive flooding of the organism with choriogenic gonadotropin shortly after the implantation of the ovum; (2) demonstration of the excreted gonadotropin on the basis of specific ovarian changes in test animals, in particular hyperemia which leads to massive hemorrhage in the enlarged follicles (blood point, the anterior pituitary reaction II), and the formation of corpora lutea (anterior pituitary reaction III).

Zondek and Aschheim [1a,b] have shown that the implantation of anterior pituitary lobe or placenta or the injection of blood or urine from a pregnant woman into an infantile rodent elicits pronounced ovarian hyperemia and ultimately leads to the formation of blood points. The hyperemia effect differs in different species of rodents. In rabbits, for instance, it cannot be elicited at all; in the infantile mouse it is ambiguous, whereas in the rat the effect is clearcut. Hyperemia is the primary visible effect of the gonadotropic hormone and is demonstrable as early as two hours after the injection of chorionic gonadotropin.

The hyperemia effect of gonadotropin on the rat ovary and the use of this reaction for the diagnosis of pregnancy have been discussed in detail elsewhere.[1e] Eighteen to twenty-four hours after the injection of 2 to 4 cc. of pregnancy urine the hyperemia effect is well in evidence and is excellently suited for use as the basis of the diagnosis of pregnancy (with a margin of error of 1 per cent). The accuracy of the rapid hyperemia test is, therefore, not inferior to that of the original Aschheim-Zondek test carried out on the infantile mouse. In a recent study we showed [1f] the important role of a time factor in the production of hyperemia as a reaction to the choriogenic gonadotropin. A much larger quantity of gonadotropin (thirty times as much) must be given in order to elicit a positive hyperemia reaction within two hours than is needed to elicit such a reaction within ten hours after injection. The relation of the minimum effective dose to the time is shown by the figures in table 1.

TABLE 1.—*Relation of the Hyperemia Unit to the Time Elapsing Between the Injection of Gonadotropin Hormone and the Reading of the Response*

Time, hours	2	4	6	8	10	11	12	18	20	24
HU *	1	1	1	1	1	1	1	1	1	1
RU †	20	15	14	1	0.5	1	2	3	4	5
IU ‡	4	3	2.8	0.2	0.1	0.2	0.4	0.6	0.8	1

* HU (hyperemia unit) is the minimal quantity of gonadotropin yielding the hyperemia effect in the rat ovary.

† RU (estrus unit) is the minimal quantity of gonadotropin eliciting vaginal estrus in the rat. The RU was determined by parallel experiments.

‡ IU was computed from RU with the aid of our local calculation factor (1/5).

It follows that a given quantity of gonadotropin, which elicits a positive reaction after ten hours, may fail to do so after only two or six hours. It is understandable, therefore, that diagnosis of pregnancy on the basis of the hyperemia response was found to be 31 per cent erroneous in our Jerusalem rat strain at two hours, and 7.8 per cent erroneous at six hours but practically free from error at twenty-four hours after injection.[1e] The highest sensitivity is obtained at ten hours, but this sometimes represents a disadvantage rather than a merit, since false positive reactions may be encountered with this high sensitivity, and the dose of urine injected must be reduced from 2 to 4 cc. to 0.2 to 0.4 cc. In practice the eighteen to twenty-four hour test is recommended.

HYPEREMIA REACTIONS OF DIFFERENT STRAINS OF RATS

The possibility requires consideration that different strains of rats may differ from one another in their ovarian response to gonadotropin. The Jerusalem strain is well suited to use in hyperemia tests. One of us[3] studied the hyperemia reaction on a local strain of rats in Europe (Berlin) from 1933 to 1935, and found it difficult to diagnose pregnancy on the basis of the hyperemia reaction with that particular strain. In Jerusalem, on the other hand, such diagnosis of pregnancy presents no difficulty. Alexander Albert has informed us in a personal communication that the strain of rats employed in the Mayo Clinic is particularly sensitive to choriogenic gonadotropin, apparently much more so than the strain used by us in the studies discussed in this paper. An investigator wishing to carry out our test for fetal death must first test his strain of rats and must compare its hyperemia unit (H U) with its estrus-eliciting unit (R U) with regard to choriogenic gonadotropin, as shown in table 1.[4] It is possible that other authors will require smaller or greater quantities of urine than those employed by us (4 cc. to 2 cc.), depending on whether their rat strains are more or less sensitive to gonadotropin than is our strain.

[4] It is easily possible to bring the hyperemia unit (*HU*) into quantitative relation to the estrus unit (*FSH*); e. g., eleven *hours* after the *injection* 1 hyperemia unit corresponds to 1 estrus unit.

TECHNIC OF READING THE HYPEREMIA REACTION

The importance of the time factor has already been stressed. Here it is sufficient to state that the hyperemia test becomes sensitive enough to be relied on only eight hours after the injection. Injections must be given subcutaneously, never intraperitoneally. In opening the rats internal bleeding must carefully be avoided, as this may sometimes render reaction uncertain or even negative. Rats should be killed with ether, chloroform or illuminating gas. The color of the positive ovaries should be red and should resemble that of the kidney, liver or spleen. A control reading must be performed some minutes after the first reading of the reaction. Hyperemia reaction of only a single ovary is always open to suspicion as an unspecific reaction and should not necessarily be interpreted as a positive reaction.

NORMAL PREGNANCY

In the diagnosis of normal pregnancy the following technic is employed with our strain of rats. We use 2 infantile rats, 3 to 4 weeks old, weighing 25 to 30 Gm. each. The first receives two injections of 2 cc. of urine at an interval of one hour; the second receives two injections of 1 cc. of urine at an interval of one hour; 250 and 500 hyperemia units (HU) of gonadotropin can be detected in this way. The reaction is read as positive for pregnancy if all the ovaries of the injected animals present a typical hyperemia; i. e., a red color similar in tone to that of kidney or spleen. In normal pregnancy the urine contains at least 500 hyperemia units per liter. If only 250 hyperemia units are detected, it is doubtful whether the fetus is alive, and a repetition of the test should be undertaken.

DISTURBED PREGNANCY

In cases of missed abortion, deficient development of the uterus constitutes an important diagnostic aid. But error may here arise from the fact that the last menstruation date is not known with certainty or is wrongly reported.

In threatened or habitual abortion accompanied by bleeding, the fetus may nevertheless still be alive and treatment may be necessary. In such cases diagnosis is extremely difficult. On the other hand, prolonged treatment of the patient is superfluous if the fetus has died. The diagnosis of extrauterine pregnancy will be discussed later.

Can the pregnancy reaction throw light on the course of a disturbed pregnancy? In our experience the use of the hyperemia titration test makes it possible to give an answer to this question in a high percentage of cases. The early months of disturbed pregnancy are generally characterized by the cessation of the placental production of gonadotropin and by an accompanying decrease in the urine titer of this hormone.

There are, however, cases in which, although the fetus has died, the excretion of placental gonadotropin (and estrogens) may still be sufficiently high to simulate the persistence of a living fetus (Zondek, 1947 [5]). In such cases the reaction will appear positive even though the fetus has actually died. Such cases will be out of our control, but this type of diagnostic error is less important than an apparent negative result in a case when the fetus is still alive. Repetition of gonadotropin tests in disturbed pregnancy should be made a routine procedure at weekly intervals. Significant decreases in the hormone levels (e. g., down to one tenth of the normal levels) will then give important diagnostic and prognostic hints.

HYPEREMIA TITRATION TEST

A significant finding in disturbed pregnancy is obtained by the use of the titration technic for the purposes of diagnosis (hyperemia titration test) as proposed by Zondek [1d] and applied by Rakoff [6] and others.

TABLE 2.—*Evaluation of the Hyperemia Titration Tests in Rats in Cases of Disturbed Pregnancy*

Rat 1 *	Rat 2 †	Rat 3 ‡	Rat 4 §	Diagnosis
+	+	+	+	Fetus living ‖
+	+	+	—	Fetus in danger; repeat reaction
+	+	—	—	Little hope; repeat reaction
+	—	—	—	Fetus dead

* In rat 1 4 cc. was injected, 250 hyperemia units per liter.

† In rat 2 2 cc. was injected, 500 hyperemia units per liter.

‡ In rat 3 1 cc. was injected, 1,000 hyperemia units per liter.

§ In rat 1 0.2 cc. was injected, 5,000 hyperemia units per liter.

‖ Between the fortieth and the eightieth day of pregnancy this result does not prove that the fetus is alive.

It has been pointed out that urine during the course of normal pregnancy, and particularly during the first five months of pregnancy, contains at least 500 hyperemia units per liter. If less hormone is found the conclusion may be drawn that the normal course of pregnancy is disturbed and that placental function is on the wane. We determine the hormone content of the urine within the range of 250 to 5,000 hyperemia units. Four infantile rats are employed (table 2): Rat 1 receives two injections of 2 cc. of urine at intervals of one hour; i. e., a total of 4 cc., equivalent to 250 hyperemia units per liter. Rat 2 receives two injections of 1 cc. of urine, a total of 2 cc., equivalent to 500 hyperemia units per liter. Rat 3 receives two injections of 0.5 cc., a total of 1 cc. of urine, equivalent to 1,000 hyperemia units per liter. Rat 4 receives two injections of 0.1 cc., or a total of 0.2 cc. of urine, equivalent to 5,000 hyperemia units per liter.

If all four rats show a positive reaction the fetus is alive. If rat 4 alone shows a negative reaction, the urine contains less than 5,000 hyperemia units and the life of the fetus is in danger. In such a case the test should be repeated a week later in order to ascertain whether there has been a further decrease in the titer. If such a decrease is observed, it is certain that the fetus has died, whereas if the titer has risen, the fetus is still alive. If rat 3 shows a negative reaction, the urine contains less than 1,000 hyperemia units per liter and there is little likelihood that the fetus is still alive. In this case, also, the test should be repeated in order to avoid error. If rat 2 shows a negative reaction, the urine contains less than 500 hyperemia units per liter and it is certain that the fetus is dead. We emphasize that in all these cases the test should be repeated, since the decision to terminate pregnancy operatively by curettage is a heavy responsibility and should not be reached on the basis of a single hormone test.

HORMONE TITER DURING THE PEAK PERIOD

Early in their investigations, Aschheim and Zondek [1b,c] showed that an enormous increase in the production of gonadotropin and in its excretion in the urine occurs a few days after the implantation of the ovum.

---

[5] Zondek, B.: Lancet 1: 178, 1947.

[6] Rakoff, A. E.: Am. J. Obst. & Gynec. 38: 371, 1939; Pennsylvania M. J. 43: 669, 1940.

Other authors[7] later showed that a second pronounced peak in horomone production and excretion occurs during the interval of forty to eighty days after nidation. During this peak period the titer rises from 10,000 to 20,000 to 100,000 to 200,000 or more hyperemia units per liter, and the use of the hormonal test for the diagnosis of disturbed pregnancy requires some caution during this time, since a value which indicates a living fetus if obtained outside the peak period may indicate the death of the fetus if observed during the peak period. For example, a 9 per cent decrease in hormone production in the peak period leads to a drop of 200,000 to 20,000 hyperemia units. Outside the peak period the latter value would be interpreted as evidence of a living fetus, whereas within the peak period it actually proves that the fetus has died. Values below 5,000 hyperemia units within the peak period are certain evidence that the fetus is dead. We arrive, therefore, at the following proviso in connection with the scheme set forth in table 2: If a positive reaction is obtained in the peak interval with all 4 rats, and 5,000 hyperemia units are, therefore, present per liter of urine, it is still uncertain whether the fetus is alive. If rat 4 gives a negative reaction (less than 5,000 hyperemia units per liter of urine), and certainly if rat 3 is negative in reaction (less than 1,000 hyperemia units per liter of urine), the test is even more reliable during the peak period than it is before or thereafter. The finding of less than 5,000 or 1,000 hyperemia units per liter of urine during the peak period indicates an enormous decrease in hormone production, and hence it points to fetal death with more certainty than if the same value be obtained outside the peak period.

EXTRAUTERINE PREGNANCY

In disturbed extrauterine pregnancy the anamnesis is not often dependable. An enlarged uterus and the presence of a tumor beside or beneath the uterus raises the suspicion of extrauterine pregnancy. If the extrauterine pregnancy is still developing, the hyperemia Aschheim-Zondek test of course elicits a positive reaction (reactions of rats 1 to 4 positive). If rupture of the tube or a tubal abortion has occurred and the fetus is dead, the placenta is only slightly functional and produces only follicle-stimulating hormone. The pregnancy reaction in such a case is negative, since luteinizing hormone is absent from the urine. Furthermore, the reaction to the hyperemia test, which depends on the combined action of follicle-stimulating hormone and luteinizing hormone, is also negative. For two weeks, however, follicle-stimulating hormone continues to be demonstrable in the urine and elicits an estrus reaction. It is, therefore, useful in the diagnosis of extrauterine pregnancy to combine the rapid hyperemia test with the original four day Aschheim-Zondek test for prolan A (FSH) in mice or, preferably, in rats. A positive follicle-stimulating hormone reaction (cornification in the vaginal smear) is then important, since it may determine whether a laparotomy should be made. We wish to emphasize, however, that in such cases the demonstration of a hematoma beside or behind the uterus is much less ambiguous as a basis for diagnosis than is the hormonal reaction. A definite diagnosis can be established in a matter of minutes by puncture of the Douglas pouch and by the aspiration of coagulated blood into the syringe. The hormonal test is necessary, therefore, only in cases in which diagnosis is difficult.

FETAL DEATH IN THE LAST TRIMESTER OF PREGNANCY

It is not definitely known whether the excretion of chorionic gonadotropin (prolan) in the urine during the last trimester of pregnancy always remains constant. Earlier reports have shown that there are cases in which excretion of gonadotropin diminishes considerably toward the end of pregnancy. Basing his analysis on his experience in Berlin, one of us (B. Z.) described the value of the gonadotropin test (Aschheim-Zondek test) in 1935 as follows[1d]:

> Only the cessation of the placental function can be established, and fetal death may be indirectly concluded from it. Hormonal tests have disadvantage that negative reactions are not reliable in the last months of pregnancy, when prolan excretion may be considerably lower and more inconstant than in the earliest weeks. In the last months of pregnancy the prolan content of the urine may sometimes be lower than *330 M.U. (660 R.U.)* per liter, so that the mouse exhibits an apparently negative pregnancy reaction.

Similar views were also adopted by Runge and Clausnitzer[8] and Fraenkel.[9]

In Palestine, where we have used the infantile rat for the Aschheim-Zondek test, we have not encountered cases of this kind, since excretion of follicle-stimulating hormone ante partum always ranged between 10,000 to 20,000 estrus-eliciting units per liter. When this value decreases considerably (to one tenth of the normal value) it indicates death of the fetus (at least in Palestine). Practice has shown that in the last trimester a negative hyperemia reaction demonstrates the death of the fetus, whereas a positive reaction may occur in spite of fetal death because the placenta is still functioning. Whether the applicability of the hyperemia titration test in diagnosis of fetal death is restricted to certain rat strains must be determined by control examinations in different countries.

The problem of diagnosis of fetal death becomes less important during the last months of pregnancy, when the auscultation of fetal heart beats becomes a reliable diagnostic aid. Still, there remain cases in which the fetal heart beats are not clearly audible. The hyperemia titration test and the determination of estrogen in the blood[10] remain of importance in such cases.

CASE MATERIAL

The observations made on the use of the hormonal test in the diagnosis of disturbed pregnancy are based on our experience in a series of 500 cases which we followed up clinically. We examined 160 cases of extrauterine pregnancy (125 ruptured and 35 undisturbed), 140 cases of threatened abortion (105 miscarriages, 35 brought to term), 200 cases of missed abortion (40 diagnosable by the first examination, 110 after two examinations and 50 after three examinations). Our results in this group warrant the conclusion that the hyperemia titration test is a valuable diagnostic aid in the determination of disturbed pregnancy.

[10] Determination of estrogen in the blood (more than 200 mouse units per liter of serum), as recommended by Spielmann, Goldberger and Frank (Spielmann, F.; Goldberger, M. A., and Frank, R. T.: Hormone Diagnosis of Viability of Pregnancy, J. A. M. A. **101**: 266 [July 22] 1933), is another important aid in diagnosis for fetal death which should never be omitted. It has, however, the following shortcomings: (*a*) The estrogen titer of the blood begins to increase only after the third month of pregnancy; hence the test is not dependable before the fourth month of pregnancy. (*b*) The estrogen titer of the blood may remain high after primary fetal death with functional placenta. Cases of this kind have been described by Zondek.[5] Our experience with the Frank test has shown that less than *200* mouse units of estrogen per liter of serum indicate fetal death.

SUMMAR

The diagnosis of disturbed pregnancy on the basis of a hyperemia titration test employing gonadotropin excreted in the urine is described. The titration in rats of our strain is carried out on four rats, which received 4, 2, 1 and 0.2 cc. of urine, respectively, corresponding to titers of 250, 500, 1,000 and 5,000 hyperemia units per liter. The fact that different strains of rats differ from one another as to their response to choriogenic gonadotropin makes it necessary to use a strain with a constant reaction and to test it for its sensitivity to chorionic gonadotropin. The proportion between the hyperemia reaction and the estrus unit (prolan A or follicle-stimulating hormone) must be established (table 1), and the quantities of urine to be injected must be determined accordingly. According to whether the strain of rats is more or less sensitive than our strain, greater or smaller amounts of urine should be used.

If all 4 rats show a positive reaction, pregnancy is normal. If rats 1 to 3 react positively and rat 4 reacts negatively, the life of the fetus is in danger. If only rats 1 and 2 react positively, there is little hope for the life of the fetus. If only rat 1 reacts positively, the fetus is dead.

The decision to treat a pregnancy operatively by curettage should never be based on a single hormonal test. In every case in which a negative reaction is observed a repetition of the test should be undertaken.

In the period from forty to eighty days after the implantation of the ovum, during which there is an enormously increased hormone production (peak period), the fetus may be dead even though all 4 rats react positively. If all 4 rats show a positive reaction to urine taken in the peak period, an unambiguous diagnosis on the basis of the titration test cannot be made. However, a result is considered even more significant during the peak period than before or after it, if rat 4 alone or together with any or all of rats 1 to 3 shows a negative reaction, since this indicates a relatively greater decrease of gonadotropin during the peak period than before or after it and therefore points with additional certainty to the death of the fetus.

During the last months of pregnancy the titer of gonadotropin is not as constant as before, so that individual fluctuations which lead to a considerable drop in the titer of gonadotropin may occur. In the case of a negative result of the Aschheim-Zondek test we therefore recommend the addition of a blood estrone determination before fetal death is diagnosed. Hormonal diagnosis during the final months of pregnancy is of importance only in cases in which fetal heart beats are not distinguishable.

The Murmur Of Heart Block.—A systolic murmur in the mitral area in heart block is only found when the heart is greatly enlarged. It is a rough murmur and it may be loud. Posture is without much effect on its intensity although it is sometimes better heard when the subject inclines to the left. A thrill is never present unless there is mitral or aortic valvular disease as well—Evans: *British Heart Journal*, October, 1947.

SURGERY OF THE SEVENTH NERVE

THOMAS G. TICKLE, M.D.
New York

Paralysis of the facial nerve, so calamitous a disfigurement in a person's life, is also an incidence of economic, social and psychologic importance, since one loses "the language of facial expression," as Duel so aptly put it. Since the face is "the mirror of the soul," many surgeons have attempted to come to the rescue by surgical procedures. To the late Sir Charles Ballance, of London, must be accredited the first recorded case of successfully operating for the relief of facial paralysis. In 1895, he anastomosed the spinal accessory nerve with the facial. (Drobnick, in 1879, performed the same operation but did not record the case, although some of his confreres wrote about it.) Brilliant as were the results of the operations, the so-called emotional response was lacking; there was atrophy of the muscles supplied by the nerve together with disfiguring associated movements.

INTRATEMPORAL FACIAL OPERATIONS

Intratemporal facial operations were devised and carried out by Ney,[1] Martin,[2] Bunnell.[3] As a matter of fact, in 1930, Bunnell using a piece of the sural nerve from the leg bridged in a gap in the facial nerve, thus restoring function to the facial muscles. There is no doubt that the great advance in treatment of facial nerve paralysis is due to the research carried on during 1929 and 1930 by Ballance and Duel. In 1932, after having worked together on animals—and not knowing of Bunnell's experiment—they advocated a direct line repair as the operation of choice in facial paralysis due to injury of the facial nerve. This operation was first performed by them in 1931 on a baby—8½ months old—who had undergone a simple mastoidectomy in which most of the facial nerve had been removed at the operation. A piece of nerve taken from the external respiratory nerve of Bell was used to bridge the dehiscence in the facial nerve.

This nerve was used for the next 2 cases, but its use was abandoned because of the difficulty encountered in locating it. The intercostal nerve was then chosen and used in the repair of the facial nerve until it occurred to Duel that, if the piece of nerve were degenerated, the time of recovery might be shortened and the end results might be better, so the anterior femoral cutaneous nerve was utilized for this purpose.

The idea of degenerating the nerve was that when a nerve is cut and allowed to remain in situ for fourteen to twenty-one days, it undergoes what is known as wallerian degeneration, thus creating a set of empty tubules. Thus the cable was prepared for the neurons to grow down through these tubules to the distal end of the cut nerve. From 1932 to 1936 the procedure was to locate the anterior femoral cutaneous nerve, sever it and wrap a piece of gold leaf around it so that it easily could be found at the time of the next operation, then allow it to remain in situ for fourteen to twenty-one

days. This piece of nerve was then used to bridge the dehiscence in the facial nerve. Heteroplastic grafts were also used as graft material in 3 cases.

Inasmuch as it required a waiting period of two or three weeks and a second operation in these cases, blood types of patients were determined on their admission to the hospital, and those with the same type were considered suitable for this operation. One patient who had the nerve severed for three weeks was operated upon on the same day as 2 other patients admitted to the hospital three weeks later, whose blood type was the same. Sufficient nerve was taken from the degenerated nerve of this patient to bridge in the gaps found in all 3 cases. The irony of this experiment was that to the 2 patients whose degenerated nerve the donor had supplied, voluntary motion was restored; while for the poor donor who had willingly given of her degenerated nerve, facial paralysis remained. One might ask: "Is it more blessed to give than to receive?"

The time of recovery was no quicker and the end results were no better than when a fresh nerve was used. The reason for this I did not know until I met Mr. Bentley in London in 1936; he, when working in the laboratory of the Royal College of Surgeons, had experimented on cats, using both fresh and degenerated grafts of the same lengths. After voluntary motion was restored, the cats were killed and the grafts examined histologically. It was found that few neurons had grown through the empty tubules and that most of them had passed along the sheath. This explains why degenerated grafts produced no better results than fresh ones.

TYPES OF CASES

The cases suitable for operation are those in which paralysis is due to an injury or to the result of a toxic infection. The latter group includes some cases of paralysis of the facial nerve in connection with acute otitis media, acute mastoiditis, chronic mastoiditis, labyrinthitis and so-called Bell's or refrigeration palsy.

To determine which cases are suitable for operation, I rely not only on the patient's reaction to faradic stimulation, but on my experience gained over a period of sixteen years in the observation of several hundred cases.

A patient with paralysis of the facial nerve in which response to faradic stimulation has been lost—and the angle of whose mouth in repose is drooping—in my opinion should have the advantage of surgical treatment. Usually the angle of the mouth on the paralyzed side is lower than on the nonparalyzed side in a complete paralysis of the facial nerve, but when the angles are about even it signifies that there is a slender connection between the nerve segments above and below the site of injury; in other words, there is enough connection left to supply tonus to the oral muscle. I have seen a number of patients in whom the response to faradic stimulation was lost regain their voluntary motion in a few months' time. These are the cases in which it is most difficult to know just what procedure to advise the patient to follow. The history of the paralysis is of great importance: When did it first appear? Was it partial or complete when first noticed? Was the onset after a simple or a radical mastoidectomy? The answers to these questions determine in large measure the advice to be given to the patient.

Complete facial paralysis immediately after either a simple or a radical mastoidectomy nearly always means that the nerve has been badly damaged or severed, while that coming on several hours or days after the operation means that the nerve had been injured either by slightly tearing the sheath and injuring a few neurons, by pushing a spicule of bone into the nerve or by a hematoma in the nerve sheath which creates an edema of the nerve, the swelling of which shuts off the impulses going from the brain to the periphery.

In those cases in which paralysis appears immediately after a simple or a radical mastoidectomy, and in which response to faradic stimulation is lost within seventy-two hours, the nerve should be uncovered and inspected. (At this point, may I emphasize the importance of using some sort of magnifying loupe or magnifying glasses when uncovering and inspecting a nerve. I did not do this myself until a couple of years ago, and I am now sure that I have often injured a nerve more than was necessary when uncovering it, and I have, as well, missed some of the finer details that originally were responsible for some of the cases of paralysis.)

In a series of cases in which paralysis followed a simple mastoidectomy, I found it often due to the fact that the operator had gone too low in trying to locate the antrum and that, failing in this, he had made a new antrum just below the horizontal semicircular canal, thus cutting the facial nerve. In most of the other cases the nerve was injured when the operator was cureting the retrofacial cells, when he was probing the antrum too vigorously, or when, on enlarging it, he had attempted to curet some granulations from the floor. In only 3 of the cases did I find the nerve to have been injured outside of the mastoid foramen.

In cases in which the paralysis followed a radical mastoidectomy, the nerve was most often injured on the floor of the antrum, probably because of the thinness of the bone covering the nerve as it makes the bend from the horizontal semicircular canal across the middle ear. In some of the cases it was injured at the apex of the facial ridge as a result of shaving down the bone too far or in removing granulations in this area, because in many of the cases there was a dehiscence in the fallopian canal. One should curet granulations in close proximity to the facial nerve with the greatest of caution, always bearing in mind the possibility that the exposed nerve may be lying under these selfsame granulations. In 1 case in which I recently operated, the operator had mistaken the canal of the tensor tympani muscle for the facial canal and had cut the nerve just below the geniculate ganglion.

Preoperative paralysis is more frequent in chronic cases than in cases of acute suppurative otitis media. One explanation for this is that most of the cases are the result of a toxic infection, while those occurring from a chronic suppurative otitis media as a rule are due to an involvement of the nerve by an osteitic process. The ratio of 3 to 1 in favor of chronic suppurative otitis media—as cited by Kettel of Copenhagen[4]—is possibly too low, especially since the number of cases of acute suppurative otitis media has been greatly reduced in the past few years by the use of the sulfonamide drugs and penicillin.

TREATMENT

Preoperative paralysis of the facial nerve in cases of acute otitis media is of itself no indication for operation, any more than are cases of so-called Bell's palsy, because the paralysis is usually due to edema or toxic neuritis; however, if there is a quick loss in faradic response, and any indication of a mastoid involvement, then operation is clearly indicated. A simple mastoidectomy should be performed without a decompression of the facial nerve. Should the paralysis still persist after a period of two months following the simple mastoidectomy, then one should consider decompression of the facial nerve.

---

[4] Kettel, K.: Facial Palsy of Otitic Origin, Arch. Otolaryng. 37: 303 (March) 1943.

In cases of chronic suppurative otitis media the situation is quite different, for there the paralysis is most often due to a propagating osteitis. I concur with others that a radical mastoidectomy is indicated. So far, decompression of the nerve in all these cases is a debated question, and I am sure that I cannot supply the answer, but I am certain that if there are loss in faradic response, a fistula in the facial canal, and any signs of an osteitis, one is justified in uncovering the nerve. If there is a faradic response and no fistula is seen, then one may be justified in waiting for about six weeks to see whether the paralysis shows signs of clearing up; if at the end of this time voluntary motion is not being restored, a decompression should be done. It is true that I have seen a number of cases in which the response to faradic stimulation was lost and in which the patient did not consent to operation; and yet the facial paralysis cleared up.

In the cases in which a decompression is done, I think that the nerve should be uncovered from the stylomastoid foramen up to the geniculate ganglion and the sheath slit over the entire exposed nerve. Prognosis in cases of paralysis of the facial nerve occurring in the course of chronic suppurative otitis media is far more serious than in cases of acute suppurative otitis media and especially so if the paralysis is treated conservatively.

TYPES OF OPERATION

The types of operation that I will discuss in this paper are those used in cases in which the nerve has been injured anywhere from the geniculate ganglion to the face: decompression; end to end anastomosis; nerve grafting. If on uncovering and inspecting the nerve one finds a slight injury to the sheath and some of the neurons, a hematoma or a spicule of bone driven into the nerve (of course, remove the spicule of bone!) all that is necessary is to slit the sheath and close the wound; if a dehiscence is found, then one must choose between doing a nerve graft or an end to end anastomosis: i. e., rerouting the nerve if possible. I prefer the nerve graft for two reasons: (1) my end results after a nerve graft have been just as satisfactory as when I did an end to end anastomosis; (2) in rerouting the nerve it is nearly impossible to get a dry ear because few of the granulations can be cleaned out of the middle ear without injuring the nerve.

The type of nerve used for the graft is of no consequence: It is the size of the nerve that is important because, if too large a nerve is used, the end results are apt to be less satisfactory. From my experience, I am not sure that using several small strands—or, in other words, what is known as a cable-graft—is not superior to using one nerve in a graft. I have used this type of graft in several cases, and nearly all have been satisfactory.

In cases in which a small strand of nerve is left, do not remove it, but slit the sheath above and below the injury and insert one or more strands. Do not use sutures in grafts or end to end anastomosis operations, unless in soft tissue, for their use tends to make more scar tissue and this possibly may be the cause of an unsatisfactory result. Glue to fasten the ends of the nerve together is unnecessary because there will be some bleeding at the time of the graft, so the patient furnishes his own "glue" which is just as good as any that is artificial, and possibly better.

An infected wound is no contraindication to doing a nerve graft or a decompression operation, for, in my experience, the results have been just as satisfactory as when there was no infection. If one waited for all infection to clear up, many of the patients with paralysis of the facial nerve never would have the benefit of surgery, especially those with paralysis following a radical mastoidectomy because in some of the cases suppuration never stops.

I wish to cite the case of Mrs. S., aged 56, who consulted me two weeks after she underwent a radical mastoidectomy that was immediately followed by a complete paralysis of the facial nerve. On opening the old cavity I found considerable granulation and some necrotic bone that had not been cleaned out at the first operation. The nerve was missing from just below the geniculate ganglion to below the horizontal semicircular canal. It required a graft of 16 mm. to bridge the dehiscence in the facial nerve, and the wound continued to suppurate; in spite of this voluntary motion was first noticed in four months' time. The suppuration continued together with the formation of cholesteatoma—in fact it became so bad that I told the patient she should consent to a second operation to which she did not agree. She continued treatment for two years until the cavity dried up, and so it has remained for the past five years. This patient has obtained one of the best results in any of my operative cases because she is 1 of 3 who can move the frontalis equally well on both sides.

CASES NOT SUITABLE FOR A DIRECT LINE REPAIR

When there is no response to galvanic stimulation, showing that the muscles either have atrophied or become fibrosed, I think that it is useless to operate. This muscle atrophying may cover a period of years. Sullivan[5] did report a case of fourteen years' standing in which cure was effected by a nerve graft, but in my experience it has been only some form of plastic operation that has obtained for the patient more symmetry when his face is in repose.

"BELL'S PALSY"

Assuming that 85 to 90 per cent of patients with "Bell's palsy" recovered spontaneously, there are 10 to 15 per cent that do not recover or recover only partially. These are the patients that should have the benefit of surgical treatment. The patients that are less apt to recover are those that suffer pain, especially over the temporal, zygomatic or postauricular region. In my opinion, all patients that lose response to faradic stimulation, and show no improvement in six weeks' time, should have a decompression operation: i. e., the nerve should be uncovered and the sheath slit from the stylomastoid foramen to the horizontal semicircular canal. It is not necessary to clean out all of the mastoid cells, but only enough to expose the descending portion of the facial canal.

In the cases that have gone on for several months or years, my attempts at decompressing the nerve have been discouraging; in cases in which I did a decompression early after the onset of the paralysis, the results have been most gratifying.

---

[5] Sullivan, J. A.: A Modification of Ballance-Duel Technique in the Treatment of Facial Paralysis, Tr.Am.Acad.Ophth. 41: 282, 1936.

FIRST SIGNS OF RETURNING FUNCTION

The patient will report that his friends and relatives say his "face is now looking better"; i. e., the mouth in repose is straighter: this can be attributed to the return of muscle tonus. The patient will often report that he feels a "creepy-crawling" sensation on the side of his face. When the patient is asked to open and close the eyes forcibly, a slight movement at the angle of the mouth will be observed. These movements will become stronger in a few weeks' time and one will be able to observe movement at the corner of the mouth without the patient's closing his eyes. The return of function will always be gradual.

POSTOPERATIVE RESULTS

The function of the frontalis muscle practically never returns, the explanation for which is supposed to be that the fewer contractile elements present in the frontalis muscle degenerate before innervation has been reestablished.[6]

The patient will not always be able to elevate the upper lip on the paralyzed as well as on the good side. There will always be a slight associated movement due to the splitting of the neurons, especially if the patient is asked to wink, and often there will be a slight twitch. This twitch, as well as the slight associated movement, often will be seen years afterward in the patients with "Bell's palsy" who have recovered spontaneously.

ABSTRACT OF DISCUSSION

Dr. Frank D. Lathrop, Boston: Dr. Tickle is to be commended for his lucid discussion of a subject that should be of primary interest to the otologic surgeon but which is gradually being assimilated by the neurosurgeons. This is regrettable in view of the fact that the well trained otologic surgeon is best prepared to restore the anatomic continuity of the facial nerve and to eradicate the pathologic process present in the middle or inner ear with which such palsies are commonly associated. It should not be expected that the physiologic function of the facial nerve will be returned to normal by the employment of any method of treating facial paralysis. Decompression, end to end suture and nerve grafting of the facial nerve, when possible, restore the physiologic function of the nerve to a variable degree in the majority of instances and permit the greatest possible return of emotional response. It is this aspect of the treatment of facial palsy that is of greatest concern to the patient. The maximum degree of emotional recovery can be attained only by the reestablishment of the original neurogenic pathway from the cerebral cortex to the facial musculature. As Dr. Tickle has mentioned, the degree of emotional recovery obtained following spinofacial and hypoglossofacial anastomoses is usually inferior to that attained with a direct line of repair and, consequently, these methods of treating facial palsy should be reserved for those cases of facial paralysis in which it is impossible to restore the anatomic continuity of the facial nerve. With respect to the importance of the faradic response in arriving at a decision as to whether the facial nerve should be explored, I am in agreement with Dr. Tickle. It should be understood, however, that failure of the nerve-muscle complex to respond to cutaneous faradic stimulation does not necessarily indicate that anatomic disruption of the facial nerve has occurred, but is indicative only of a physiologic interruption even though the nerve may be anatomically intact. Consequently, when the facial nerve is anatomically intact and exhibits a negative faradic response, spontaneous recovery from the palsy is not precluded. Experience with a number of battle casualties presenting facial paralyses revealed that in many instances the nerve-muscle complex failed to respond to faradic stimulation when tested in the usual manner but gave a positive response when stimulated with the patient under general anesthesia. This would seem to indicate that failure to obtain a positive response when the test is performed in the usual manner may be owing to inability of the patient to withstand the pain of a faradic stimulus of sufficient intensity to obtain a positive response without benefit of a general anesthetic. All patients tested in this manner whose course I have been able to follow had recovery subsequently from their facial palsy.

Dr. J. A. Sullivan, Toronto, Canada: What is important in the use of a graft is this singular fact, which can be most vividly seen under the dissecting microscope, that it is easier to mobilize and get accurate coaptation of nerve ends with a degenerated graft than it is with a fresh one, and that is my particular reason for preferring the use of a degenerated graft. The length of the graft is important. The entrance of neurofibrils through the proximal end of the graft is, as a rule, not impeded, but what does occur is the formation of endoneural scar at the distal end of a graft; with a long graft more time is afforded for this pathologic formation to occur. In a short graft this condition does not pertain. I agree with Dr. Tickle on the point that he utilizes for the determination of when and when not to operate. To be absolutely sure of the faradic response, it is necessary to expose the nerve directly and observe the results. Involvement of the seventh nerve may have been due to a recurrent acute reaction superimposed on the chronic process producing the paralysis. In regard to rerouting of the nerve, I most emphatically agree. I do not believe that the nerve should be rerouted. I prefer the use of a single nerve as a graft to that of the cable graft. I have done considerable work with the use of plasma, and I consider it a great adjunct and advise that it be used routinely in the approximation of graft to nerve. One only needs to observe this under the dissecting microscope to become firmly convinced of its practical value. As power cannot be restored to muscles which have undergone fibrous atrophy, absence of galvanic response is a contraindication to any operative treatment directed to the nerve supply. What is perhaps less well appreciated is the possibility that fibrosis may involve parts of the small muscle bundles of the facial musculature, interfering with that synergic contraction within the larger functional muscle groups that gives rise to the infinite variety of expressive movements. This fibrosis may also be responsible for the nonreturn of movement to the frontalis muscle after the graft operation; i. e., in cases in which the muscle is necessarily denervated for a relatively long time, in contrast to the early return of movement in this muscle in cases in which recovery occurs without surgical intervention.

DR. THOMAS G. TICKLE, New York: I agree with Dr. Lathrop that surgical treatment of the facial nerve should be in the hands of the otologist. As he mentioned, the surgeons do not know a mastoid as well as an otologist. Dr. Sullivan thinks a degenerated nerve better than a fresh one, but my results have not been any better. Maybe it is because I have not been using the dissecting microscope, but in my approximation, I think it has been just as good in a fresh graft as a degenerative graft. In monkeys, my colleagues and I used to cut the nerve and test them out every hour. We found that the response would be lost in forty-eight to seventy-two hours after the nerve had been cut. We never found one case in which the period was longer than seventy-two hours.

Medical Officers Certified By Boards.—During the last few months forty-two officers of the Regular Army Medical Corps have been certified by American Boards as a result of the Army's training program. A total of fourteen specialties are represented in this number, internal medicine leading with a total of seventeen certifications.

ANTERIOR OR PERINEAL PILONIDAL CYSTS

TOM E. SMITH, M.D.
Associate Professor of Proctology, Southwestern
Medical College
Dallas, Texas

When the term "pilonidal cyst" is used one immediately thinks of the pathologic hair-bearing cysts seen in the vicinity of the midline coccygeal region. The reporting of thousands of these cases in the literature, plus time, has made this anatomic location conventional, and it is difficult to think of a pilonidal cyst occurring in any other site.

In 1943 and 1944 4 cases of pilonidal cyst were seen which were located in the perineum, several inches anterior to the anal verge. These cases were interesting diagnostic problems since they were all sent to the Ano-Rectal Surgical Section of Brooke General Hospital with a diagnosis of "anterior anal fistula." Three patients had what appeared to be external fistulous orifices in the left anterolateral perianal quadrant, and 1 had an orifice located in the right anterolateral perianal quadrant. The orifices were situated from 1 to 3 inches (2.5 to 7.6 cm.) from the midline.

At first it would seem easy to differentiate these perineal cysts from anal fistulas by simple palpation, but actually the results of palpation are as confusing as they are enlightening. Palpation in these cases failed to reveal an indurated cord leading into the anal canal. Occasionally anal fistulas with slow abscess resolution present the same picture. The same thing is also seen in fistulas that can be felt going toward the anal verge but which dip deep and pass between the outer and middle lamellae of the external anal sphincter muscle. Therefore palpation was not a conclusive diagnostic criterion in these cases.

At this stage some will say that use of the silver probe would make the decision, but probing gave little information since a probe passed into an unresolved fistulous abscess will pass in many directions just as it does when it is inserted into a cystic cavity. Here a word regarding sympathy for the patient is in order. Probing near the anus in the unanesthetized patient is a painful and sweat-provoking procedure and is one which should be condemned. It certainly puts a strain on the relationship between patient and doctor and is apt to make the patient feel that he is in the hands of an unthoughtful surgeon. If probing is considered essential toward diagnosis by the surgeon, then saddle block anesthesia should be used. This will relieve the patient of pain and tend to lessen false interpretations by the surgeon.

The bacteriologic study of the exudate from all fistulas was a routine on the surgical service at Brooke General Hospital, and this measure was found to be of importance in the differential diagnosis. Lieut. Col. Max Levine, Chief of the Bacteriology Section, advised applying a layer of tincture of iodine over the orifice area and allowing it to dry. Then with sterile technic the exudate was expressed and studied. Coliform bacilli were not found in any of these cases of perineal pilonidal cysts, while they were universally found in the exudate from the external orifices of anal fistulas.

Methylene blue was instilled into these patients after saddle block anesthesia. The anesthesia was used to prevent the stimulation to contraction of the powerful external anal sphincter muscle by the injection of methylene blue under pressure. In no case did the methylene blue appear at the dentate line in the anal canal. The blue solution was then washed out of the cavity with hydrogen peroxide. This was followed by injection of a chloriodized peanut oil preparation and the taking of flat plate roentgenograms. The roentgenograms showed a pooling in the perineum with no tract leading toward the anal canal.

The conclusive proof that these perineal cysts were of the pilonidal type was found at operation. Each cyst was strutted with methylene blue–hydrogen peroxide solution and excised en bloc. After the cysts were opened, hair was found in the cavity, and microscopic study later revealed the same structure as that seen in coccygeal pilonidal cysts.

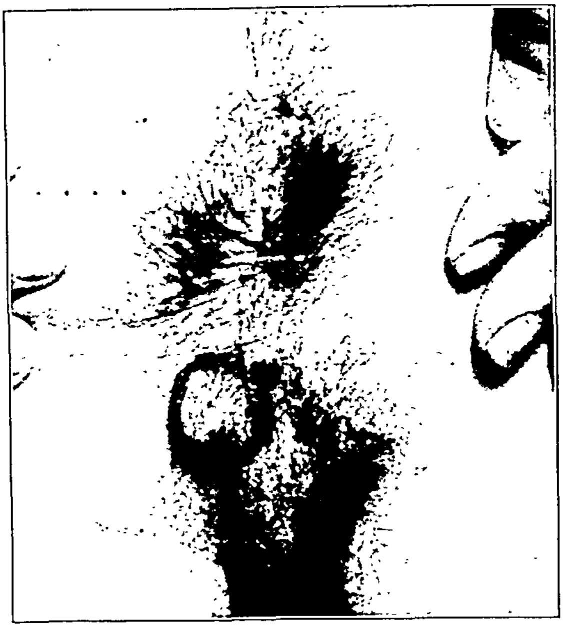

Fig. 1 (case 1).—Anterior pilonidal cyst. Limits of induration are shown by the dark circle. The cystic orifice is seen near the center of the circle. Note that all of the cyst is located on the left of the perineal midline.

These anterior or perineal pilonidal cysts should not be confused with postrectal or presacral dermoids, since they are different entities entirely. The postrectal dermoids are occasionally misdiagnosed as a conventional pilonidal cyst because in some cases their external vents come to the surface in the region of the midline coccygeal zone. A pilonidal cystectomy is done which is then followed by recurrence, since the true cyst was undetected. Postrectal dermoids should be thought of in cases of repeated recurrence following coccygeal pilonidal cystectomies. This was elucidated by Dr. Frank H. Lahey in 1934.[1]

SYNOPSES OF CASES

Case 1.—The patient, a private aged 35, was seen in April 1943. The external orifice was 2½ cm. to the left of the anterior midline approximately 6 cm. from the anal verge (fig. 1). The

---

Read before the Section on Gastro-Enterology and Proctology at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 12, 1947.

[1] Lahey, F. H., and Eckerson, E. B.: Presacral Dermoids, Am. J. Surg. 23: 30, 1934.

previously described procedures were done to differentiate from an anterior anal fistula. On April 6, with the patient under caudal transsacral anesthesia, the cyst was removed with electrosurgical technic and the perineal wound was left open. Light packing with an emulsion of sulfathiazole was done. The wound healed uneventfully in *thirty-five days.* The microscopic pathologic report stated "The section has apparently been removed with cautery and the edges are charred. The tissue submitted is hair bearing and is partially covered by stratified squamous epithelium."

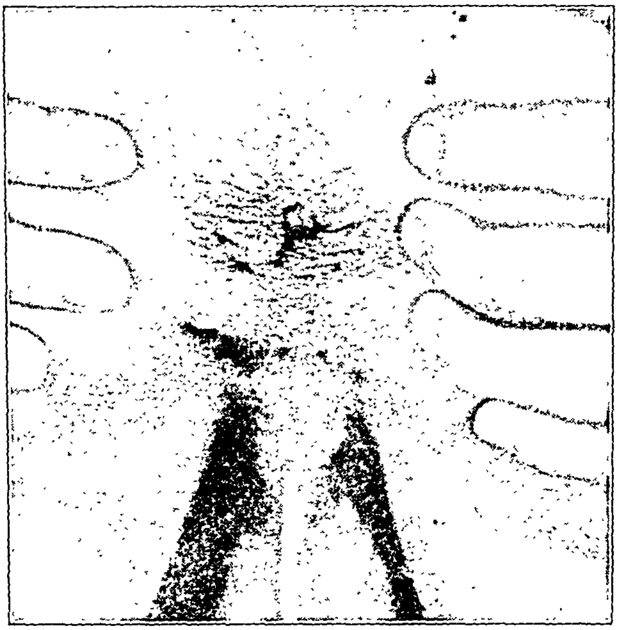

Fig. 2 (case 3).—Anterior perineal pilonidal cyst.

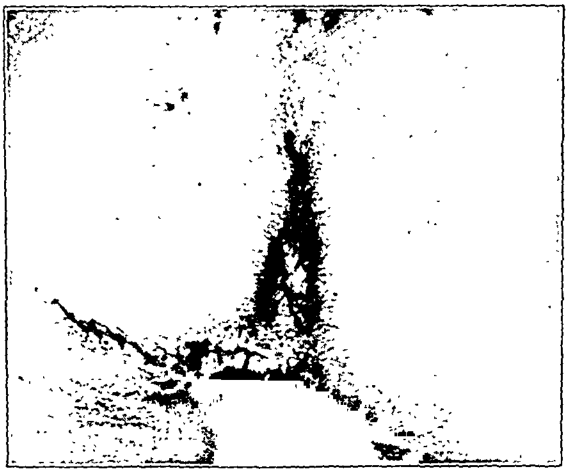

Fig. 3 (case 3). Showing interrupted cotton suture skin closure (closed method)

CASE 2.—The patient, a first lieutenant aged 29, was seen in April 1943. He had both coccygeal and perineal pilonidal cysts. A coccygeal pilonidal cystectomy was done on March 31, 1943, by the "closed method" devised by Dr. F. C. Shute, who was on active duty at Brooke General Hospital at that time. On April 30 the perineal pilonidal cystectomy was performed by the closed technic with cotton sutures. The perineal wound healed per primum. Sutures were removed on the seventh postoperative day. The microscopic pathologic report of the perineal pilonidal cyst stated "Multiple sections are taken to show various portions of a sinus tract. Throughout the major portion of its extent its wall is composed of dense fibrous tissue infiltrated by numerous lymphocytes and mononuclear cells. Near the center there is recent suppuration, associated with the formation of foreign body giant cells. At one or two points hair follicles are noted in the wall." A later report stated: "Multiple additional sections have been examined and very strongly suggest that an epidermal component is present in the cyst."

CASE 3.—The patient, a private aged 32, was examined in July 1944. Figure 2 shows what appears to be an anterior anal fistulous orifice. Perineal pilonidal cystectomy was done on July 13 with the patient under caudal transsacral anesthesia, the sharp dissection technic being used. Closure was done with chromic 1 and plain 0 surgical gut for deep suture and 70 cotton for the skin. Figure 3 shows the wound on the fifth postoperative day. The wound healed by primary intention. Figure 4 shows the excised cyst after opening for inspection. The microscopic pathologic report follows: "Multiple sections were cut from the tissue submitted and show a marked nonencapsulated zone of vascular granulation. In some parts this is apparently cystic. In one of the sections an occasional tangential fragment of hair is present."

CASE 4.—The patient, a sergeant aged 25, presented himself in October 1944 with a diagnosis of an anterior anal fistula. However, the induration and other findings led to a preoperative diagnosis of anterior *perineal pilonidal* cyst. Block dissection was done on October 6; the closed technic was used, with interrupted sutures of plain 00 surgical gut for deep closure and interrupted dermal sutures for the skin. The sutures were removed on the seventh postoperative day. The gross pathologic report was: "The specimen consists of a previously sectioned segment of skin with subcutaneous tissue that measures 3 by 0.7 by 0.7 cm. The skin surface is rough and slightly pink stained. Sectioned surfaces show an opened smooth membrane-lined area that measures approximately 12 mm. in length, from which project several long hairs." The pathologist commented: "The findings are compatible with a cyst partially lined with stratified squamous epithelium and partially by granulation tissue. The etiology of the process is not determined."

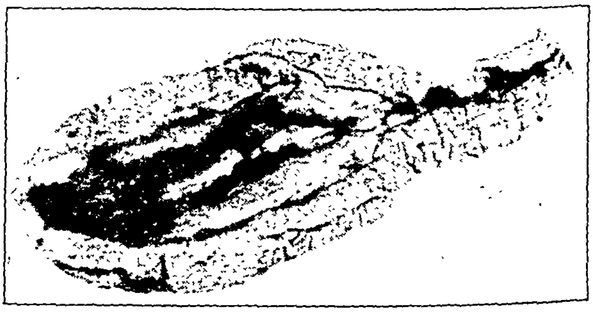

Fig. 4 (case 3).—Specimen after being opened.

Since hair was removed by me from each of these perineal cysts, it can be emphasized that these were hair-bearing or pilonidal cysts. Since hair is not always found in coccygeal or posterior pilonidal cysts, having either been washed out by suppurative exudate or been pulled out by the patient or examining doctors, it is possible in the future that anterior pilonidal cysts will be seen which are void of hair.

As none of these cysts had their openings in the midline and all had the major part of the cystic tissue on either side of the midline it seems difficult to explain them etiologically as being faulty midline ectodermal invagination, as suggested by Bookman in 1924.[2] The neurogenic theory of formation of pilonidal cysts as propounded by Tourneaux and Herrmann[3] in 1887 is dealt a death blow when pilonidal cysts are found on the anterior part of the perineum, for no embryologic vestige of the neural canal is normally located there. The soundest etiologic explanation of coccygeal or posterior pilonidal cyst has been given by Fox,[4] and his investigations and deductions could also account for the finding of pilonidal cysts in the perineum. Fox stated "that pilonidal sinus is a derivative of skin ectoderm and not neurogenic or enteric in origin, that the structures forming the sinuses are derived by a process of ectodermal invagination from the skin surface at the time and in cells destined to form skin appendages (hair and glands) during the third and fourth months of embryonic life and that its mode of origin and the analogy drawn between this structure and the special scent' gland in the sacrococcygeal region of birds and amniotes suggest the probability that the sinus represents a vestigial skin appendage developing at puberty —hence the age distribution of pilonidal sinus."

---

[2] Bookman, M. R.: Treatment of Sacro-Coccygeal Sinus (Pilonidal Sinus), New York State J. Med. 24: 204, 1924.

SUMMARY AND CONCLUSIONS

Since no report could be found of the location of pilonidal cysts in the anterior part of the perineum, 4 such cases were reported. The differential diagnostic points between anterior anal fistulas and anterior perineal pilonidal cysts were outlined. It was emphasized that anterior perineal pilonidal cysts were not to be confused with presacral dermoids (postrectal dermoids). Synopses of the cases involved were presented, with pathologic observations emphasized. Etiologic explanations were discussed.

SURGERY OF THE LOWER BOWEL

Preparation and After-Care of the Patient

HARRY E. BACON, M.D.
Philadelphia
and
ROBERT J. ROWE, M.D.
Dallas, Texas

The preparation and postoperative management of the patient undergoing surgery of the lower bowel has assumed a position of increasing importance to both the surgeon and the gastroenterologist during the past decade. The results of the clinical application of certain factors responsible for this metamorphosis have been well demonstrated in our series of patients with lesions of the colon and rectum, including over 600 with malignant growths in this region, and are summarized in table 1.

It is our opinion that this reduction in mortality following surgical procedures of this magnitude has been due largely to the advances that have been made in the preparation and after-care of these patients rather than to refinements in surgical technic. In this presentation it is possible to discuss only a few of the most important advances, which in our opinion have been chiefly responsible for these results.

PREOPERATIVE EVALUATION AND PREPARATION

In order properly to prepare the average patient for major surgery of the colon and rectum, it is preferable that he be hospitalized for several days prior to the operative procedure. During this time, an effort is made to evaluate the patient as a surgical risk and, so far as it is possible, place him in optimal nutritional, fluid, electrolyte, nitrogenous, and vitamin balance while the bowel is being prepared for surgical treatment. Efforts are made to evaluate hepatic and renal function.

TABLE 1.—*Deaths in Series of Patients with Lesions of Colon and Rectum*

Total	488	26	5.3

* Abdominoperineal proctosigmoidectomy.

The presence of hepatic dysfunction was noted by one group[1] in 25 per cent of patients with gastrointestinal cancer. On a small scale similar studies were carried out by our department, but confirmation of such definite evidence of dysfunction was not demonstrable. It was interesting to note that contrary to previous reports,[2] the alkaline serum phosphatase reaction was normal in 10 patients with massive metastases to the liver. Occasionally definite evidence of hepatic dysfunction has been demonstrated by the sulfobromophthalein sodium or cephalin flocculation tests. If there is evidence of hepatic damage operation is delayed until an attempt has been made to remedy the condition.

TABLE 2.—*Preoperative Evaluation*

Routine Studies	Elective Studies

high protein intakes so as to provide an erythrocyte count of 4,500,000 with a concomitant hemoglobin of 80 to 90 per cent, hematocrit readings of 40 or above, and normal serum protein values. A minimum of 1,000 cc. of blood is made available for each prospective bowel resection. Although the average blood loss from abdominoperineal resection is only 450 to 500[3] cc., it has been our experience that at least 1,000 cc. of blood should be given during most abdominoperineal resections. This prevents shock and has enabled us to maintain a positive nitrogen balance with greater ease postoperatively.

In impending obstruction, or as an adjunct to primary resection, the mercury-weighted Miller-Abbott tube has proved eminently useful. However, if definite obstruction is present proximal enterostomy is advisable. In this group of patients it is imperative to establish fluid and electrolyte balance before surgical treatment is instituted.

A fluid intake of 2,500 to 3,500 cc. is maintained daily and renal function is tested by checking the specific gravity. If at least one specimen is not obtained with a specific gravity of 1.020 tests of renal function are initiated.

500-1,000 mg. ascorbic acid daily
100,000 units of vitamin A daily

* "Delcos granules" supplied by Sharpe & Dohme, Inc. Each hundred grams contains whole protein 50 Gm. and carbohydrate 30 Gm.

† "Protenum," supplied by Mead Johnson and Company.

‡ "Unicaps," supplied by The Upjohn Company. Each capsule contains nicotinamide, 20 mg.; vitamin A, 5,000 U. S. P. units; vitamin D, 500 U. S. P. units; ascorbic acid, 37.5 mg.; thiamine hydrochloride, 2.5 mg.; riboflavin, 2.5 mg.; pyridoxine hydrochloride, 0.5 mg., and calcium pantothenate, 5 mg.

PREPARATION OF BOWEL

Careful preparation of the bowel prior to surgical treatment with antibacterial agents and proper diet without purgation have undoubtedly been a significant factor in lowering the mortality following resection of the colon and rectum. The presence of avitaminosis and malnutrition—particularly hypoproteinemia—in patients with malignant growths of the gastrointestinal tract has been demonstrated repeatedly.

It is essential, therefore, to provide a well balanced, high protein, high caloric, high vitamin diet which yields no residue but contains adequate minerals and vitamins. Table 3 contains a diet which has served this purpose adequately.

Rectal irrigations are frequently necessary. For this purpose a solution is used containing 6 Gm. of phthalylsulfathiazole and 10 Gm. of sodium bicarbonate.

It is unnecessary to discuss in detail the use of the sulfonamide compounds. Phthalylsulfathiazole is our preference routinely, given in doses of 0.1 Gm. per kilogram of body weight daily. In some instances, when a moderate degree of obstruction is present, it has been proved advisable to use succinylsulfathiazole, since it possesses a laxative effect. Mention has been made that phthalylsulfathiazole decreases the bacterial count in fecal material to the point that synthesis of vitamin K is interfered with and increases hemorrhage during and after the operation. Such has not been our experience, but vitamin K is administered preoperatively and also postoperatively for twenty-four hours.

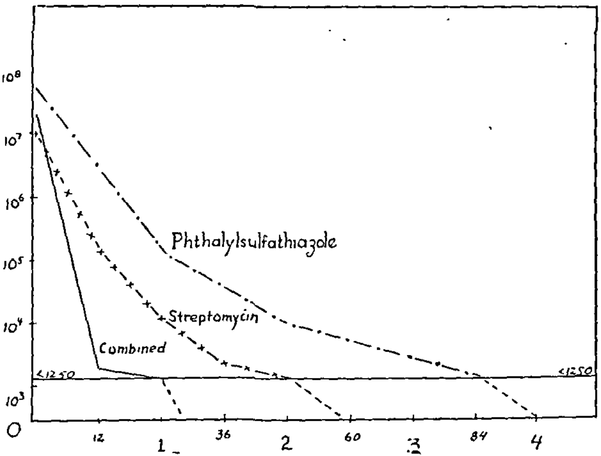

Chart 1.—Average coliform counts. The dosage of phthalylsulfathiazole was 0.1 Gm. per kilogram of body weight daily; that of streptomycin, 2 Gm. daily.

In regard to the use of agents for lowering the bacterial flora of the colon, it might be interesting to relate that our department, in conjunction with Professor Earl Spaulding, head of the department of bacteriology, and Miss Dorothy Madajewski, has been investigating the efficacy of oral administration of streptomycin.

The effectiveness of phthalylsulfathiazole, streptomycin, and a combination of the two in reducing the coliform organisms in feces is shown in chart 1.

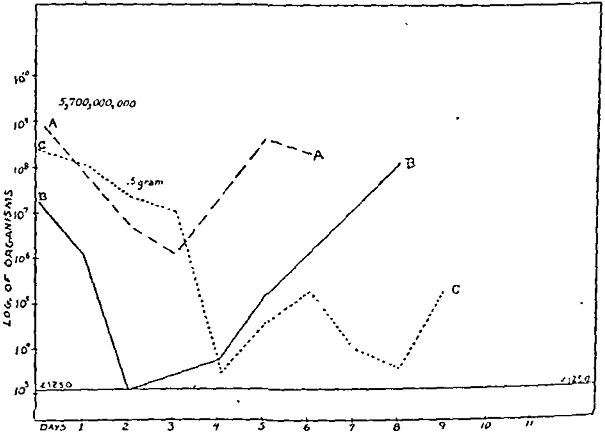

Chart 2.—Reversion curves. *A*, reversion of anaerobic gram negative bacillus; total bacterial count, combined therapy. *B*, reversion of Aerobacter aerogenes following combined therapy. *C*, Reversion following 0.5 Gm. of streptomycin.

All patients in this study had cancer of the colon or rectum. Results have not been absolutely uniform with any of the agents. In 1 patient of a series of 12, the count remained moderately high (12,500 organisms) after phthalylsulfathiazole had been used for ten days. One patient out of 10 failed to respond to streptomycin after five days' therapy. In the combined group, our study is incomplete and more detailed results will be published later. However, 2 patients

3. Coller, F. A., and Crook, C. E.: Blood Loss in Surgical Operations, J. A. M. A. **126:** 1 (Sept. 2) 1944. Pack, G. E.; Oppenheim, A.; Abels, J. C., and Rhoads, C. P.: Estimation and Significance of Blood Loss During Gastrointestinal Surgery, Am. J. Surg. **119:** 871, 1944.

of 9 did not respond in the usual manner. In both instances the count was less than 1,250 within forty-eight hours, but in 1 patient it fluctuated between 60,000 and 1,250 for eight or nine days before remaining below 1,250; in the other patient the count returned to more than 100,000,000 (chart 2, Patient B). A pure culture of a very resistant Aerobacter aerogenes was isolated, and later proved to be definitely pathogenic. From the studies it appears that combining streptomycin and phthalylsulfathiazole for preoperative preparation of the bowel has advantages over the use of either of the substances alone. This is true only with regard to the coliform bacteria. Other studies as well as recent investigation of our own with regard to total bacterial counts tend to disprove the theory that the coliform count is a reliable index to the colon bacterial flora. In fact further study may reveal that administration of the sulfonamide compounds or antibiotics may be harmful, although this is not our opinion at present. Reversion occurred in 2 patients when streptomycin was administered in daily doses of 0.5 Gm.

Chart 2 demonstrates the reversion (or resistance) that may develop after the use of combined therapy. This occurred after prolonged use of the drugs, and although our studies are not complete at present it would appear that combined use of these substances preoperatively should be limited to forty-eight to seventy-two hours.

POSTOPERATIVE MANAGEMENT

Regardless of the manner in which the patient has been prepared or the type of operative procedure performed, competent and alert postoperative care is necessary to maintain low mortality rates following resection of the lower bowel.

NUTRITION

In recent years nutrition of the surgical patient has attained a position of paramount importance. Intensive research in this field has resulted in the monumental discovery of protein hydrolysates which could be administered parenterally. Similar advances have been made in parenteral vitamin therapy in the use of plasma and blood, and our knowledge of water and electrolyte balance has been extended. These new advances have enabled the surgeon to eliminate the period of acute starvation following abdominal operations as well as to feed patients parenterally for long periods of time when necessary.

FLUID BALANCE

In estimating fluid requirements it is necessary to consider the average daily intake, the loss of fluids from the body—the estimable loss from the kidneys, gastrointestinal tract and Wangensteen suction, as well as the insensible loss from the skin and the lungs.[4]

In our experience the urinary output and clinical evaluation of the patient have been the most valuable indices to the status of the body water balance. In conjunction with this the erythrocyte count, hemoglobin, hematocrit, serum protein, carbon dioxide content, serum chlorides, urinary chlorides and specific gravity and p_H of the urine are necessary determinations for rational fluid replacement. All fluid losses from suctions, ileostomies, fistulas, etc., must be computed and replacement of similar electrolytic substances instituted.[5]

Attention should be called to the danger of salt intoxication,[6] since it has been demonstrated that patients do not tolerate large amounts of salt during the early postoperative period.

In the average postoperative bowel resection with gastric suction, 2,500 to 3,000 cc. of fluid containing 150 Gm. of carbohydrate and 9 Gm. of salt will maintain fluid and electrolyte balance with a urinary output of 1,000 cc. of 1.015 specific gravity.

PROTEIN NUTRITION

Proteins are the most important component of food, being essential for growth and repair of injury to the body.[7] The frequency with which hypoproteinemia occurs in patients with malignant growths of the gastrointestinal tract has been demonstrated repeatedly. Several[8] groups have called attention to the important part that protein metabolism, particularly hypoproteinemia, plays in wound healing, predisposition to shock, postoperative edema in wounds and surrounding suture lines, increased susceptibility to infection, anesthesia and hepatic dysfunction. It is therefore essential that an attempt be made preoperatively to increase protein reserves, and postoperatively to maintain a positive nitrogen balance. In our patients this is done with plasma, whole blood, and 60 to 120 Gm. of protein hydrolysate daily. Table 4 reveals the average regimen that is followed in patients who have undergone abdominoperineal resection.

TABLE 4.—*Regimen for Average Patient on First and Second Postoperative Day Following an Abdominoperineal Proctosigmoidectomy with Gastroduodenal Suction*

First day:	
1,000 cc.	5% dextrose in 0.9 per cent NaCl solution
2,000 cc.	5% dextrose and 5-6 per cent protein hydrolysate in water, or 0.2 per cent NaCl
3,000 cc.	Total intake, with 150 Gm. carbohydrate: 60-120 Gm. protein: 9-11 Gm. NaCl
Second day:	
1,000 cc.	5% dextrose in 0.9 per cent NaCl solution
250 cc.	Sixth-molar solution sodium lactate
250 cc.	Blood plasma and/or
1,500 cc.	5% dextrose in water with 60 to 90 Gm. of protein hydrolysate
3,250 cc.	Total intake, with 125 Gm. carbohydrate: 60-120 Gm. protein: 9 Gm. NaCl

USE OF ANTIBIOTICS

Penicillin is employed routinely after bowel resections in doses of 30,000 units every three hours. If contamination is present sulfones are used intravenously until they are tolerated by mouth.

In the presence of infection the type of causative organism and its susceptibility to the antibiotics and sulfonamide compounds is determined before therapy is instituted.

THROMBOEMBOLISM

Since the introduction of the newer antibiotics and sulfonamide compounds, mortality from infection is almost an entity of the past. Hence the attention of surgeons has been drawn to other less frequent causes of death. Thus an unprecedented interest has arisen in thromboembolic disease. Although not at first apparent, the justification for this is demonstrated in our series. Five deaths due to pulmonary emboli occurred in 439 operations on the bowels.

For a period of over two years a rigid prophylactic regimen has been instituted. The results are shown in table 5.

TABLE 5.—*Thromboembolism*

	Bowel Operations *	Fatal Pulmonary Emboli	Mortality
Prior to August 1945....................	439	5	1.1%
Subsequent to August 1945............	246	0	0

Prophylactic measures:

1. Early active exercise of legs hourly when awake
2. Early unassisted movement in bed
3. No pillows under knees
4. Vigilant daily examinations for early signs of deep venous thrombosis of lower extremities
5. Early ambulation, from 2 to 5 days, depending on the operation
6. Elastic bandages in selected patient

ndications for anticoagulant therapy:

1. Tenderness over the deep calf veins; (*a*) Homan's sign; (*b*) Moses' sign
2. Unexplained concomitant rise in temperature and pulse; (*a*) Allen's sign
3. Previous embolic phenomena
4. Evidence of superficial or deep thrombophlebitis
5. Circulatory disturbance of the lower extremities
6. Cardiac disease

Therapy

1. Combination of heparin and "dicumarol": 20 cases
2. Femoral ligation: 1 case: no mortality

* Largely abdominoperineal proctosigmoidectomies.

OTHER POSTOPERATIVE COMPLICATIONS

With proper preoperative care and attention to replacement of blood lost during the operation, shock is encountered seldom. It has been our experience that whole blood is much more efficient in the prophylaxis and treatment of shock than plasma. Hemorrhage has not been encountered, although its occurrence after the use of sulfonamide compounds has been mentioned. For this reason synthetic vitamin K is used routinely for twenty-four to thirty-six hours postoperatively.

The incidence of adynamic ileus has been minimal since intestinal suction and high concentrations of oxygen have been used routinely postoperatively until peristalsis returns.

Atelectasis is one of the most common postoperative complications in our experience and is manifested early by a sharp rise in temperature. Treatment should be immediate removal of the bronchial obstruction by suction with intratracheal catheter or bronchoscopy.

Postoperatively continuous drainage of the bladder and frequent irrigations are used until vesical function has returned to normal as indicated by cystometry and the amount of residual urine present. Prostatic resection has not been indicated.

In regard to wound care and wound complications it may be said that with the use of alloy steel wire for closure, plus Babcock sump drainage, sulfonamide compounds, the antibiotics and vitamin C the incidence of complications has been reduced to a minimum.

SUMMARY AND CONCLUSIONS

In a series of four hundred and eighty-eight bowel resections, three hundred and forty-six were performed prior to January 1946 with 15 deaths (6.4 per cent) and one hundred and forty-two subsequent to that date and prior to May 12, 1947 with no deaths. It is our opinion that this reduction in mortality was due to careful preoperative evaluation, preparation and postoperative care.

Preoperative evaluation and preparation require several days, during which time an attempt is made to create optimal nutritional, fluid, electrolyte, nitrogenous and vitamin balance and a clean, tranquil bowel.

A combination of phthalylsulfathiazole and streptomycin constitutes the best preoperative antibacterial agent. The latter should be used for only forty-eight to seventy-two hours, since reversion occurs frequently.

Nutrition of the patient with particular attention to protein metabolism fluid and electrolyte balance is essential postoperatively.

Evidence is presented that intensive prophylaxis and anticoagulant therapy are adequate to prevent the occurrence of fatal pulmonary emboli.

Other postoperative complications are briefly discussed.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. SMITH, BACON AND ROWE

DR. FRANK H. LAHEY, Boston: I would strongly urge on gastroenterologists that they do not send these patients to surgery so full of barium. There is nothing that makes it more difficult to resect a colon. Our gastroenterologists have done their utmost in these cases with castor oil and other vigorous intestinal evacuants, but it takes time and wastes beds in the hospital, and unless the patients are sent home, in many of the cases, and given time, they cannot be thoroughly emptied of their barium. There should be better planning as to the introduction of barium into the alimentary canal. I have had so much barium to deal with that in some of these cases the only way I could prevent the patient from being closed and reopened was to milk the barium into segments I could resect, in order to get rid of it, particularly in the sigmoid and in the rectum, where the lesion could be handled. I am sure that the administration of the sulfone group of drugs and streptomycin is desirable; however, yesterday at the Section on Surgery, mortality rates were reported to be about the same in the hands of those who employ them and in those who do not. On the other hand, we do not often employ suture methods in the large bowel and certainly not in the anastomoses in the pelvis and in the abdominal sacral region, and so it is of less importance to us. Regarding emboli, we have certain rules. We are not the ardent advocates of vein ligation that many others are. We have been able to maintain satisfactory figures as to pulmonary emboli with the use of anticoagulants. We have a rule that if the patient has had a two stage operation and there is a thrombosis or sublethal infarct emboli, in those cases a bilateral ligation must be done before the second major operative procedure is undertaken. There is one other thing. We must realize that many of these persons who are being submitted to these major surgical procedures are receiving transfusions while under an anesthetic; this does away with the opportunity to introduce small amounts of blood in order to observe the early evidence of mismatching. There are no evidences of mismatching in patients under anesthesia, and I believe if we knew the number who have died due to improper matching, from transfusions administered while under an anesthetic, it would be tremendous. We have had a small number. Think of the opportunity of a girl's passing through the ward, picking up several blood specimens; think of the opportunities for mistakes that can be made, and what actually hangs on them—a life, if a wrong tube is used and mismatching results. For that reason double matching is necessary in order to be absolutely safe in this group of cases.

Dr. Edgar J. Poth, Galveston, Texas: As regards streptomycin, I agree with Drs. Bacon and Rowe concerning the development of resistance.' It occurs in the course of three or four days; when streptomycin is used, it can be used for only a short period of time. Succinylsulfathiazole and phthalylsulfathiazole should be given for a minimum of seven days in full therapeutic doses to effect adequate preoperative preparation. If phthalylsulfathiazole is given, the simultaneous administration of a mild purgative is usually required to obtain an empty bowel and satisfactory mechanical preparation. Furthermore, the postoperative administration of these two drugs for twelve days will largely eliminate infections of the urinary tract. These slides illustrate the influence of succinylsulfathiazole and phthalylsulfathiazole on healing following anastomosis of the colon. The first slide demonstrates the edema of the mucosa extending for an inch (2.5 cm.) on either side of the line of suture. In the next slide it is obvious that the edema is present in only one or two folds of the mucosa to either side of the anastomosis. This animal received succinylsulfathiazole for two weeks preoperatively effecting a prolonged attenuation of the bacterial flora. These photomicrographs of sections from the line of suture on the third postoperative day show (in the control) edema, extensive polymorphonuclear infiltration, and no evidence of revascularization or fibroplasia. The next slide shows early healing with orderly fibroplasia, revascularization, slight edema and moderate polymorphonuclear infiltration. In brief, succinylsulfathiazole and phthalylsulfathiazole favor healing of the bowel.

Dr. Robert J. Rowe, Dallas, Texas: I should like to emphasize that prolonged oral administration of streptomycin may be very dangerous. This was brought forcibly to our attention when a fatal pelvic and abdominal peritonitis occurred in the patient whose stools contained the resistant Aerobacter aerogenes preoperatively. The same organism was isolated at autopsy and found to be resistant to the sulfonamide compounds as well as to streptomycin. No organisms resistant to sulfonamide compounds or streptomycin were isolated from the preliminary specimens of stool. This brings up the possibility that streptomycin may also increase the resistance of certain coliform organisms to the sulfonamide drugs. This series is entirely too small for definite conclusions. However, if streptomycin-resistant organisms occur in one third of the patients, the administration of streptomycin for longer than forty-eight hours would seem to be contraindicated. Since these results are at a variance with those published by another group, further study of this problem is indicated before the value of oral streptomycin can be estimated.

INNOCENT MITRAL SYSTOLIC MURMURS. The situation and distribution of these murmurs and the effects upon them of a change in posture and deep breathing make it possible to tell them from the murmurs of organic heart disease. The phonocardiograph confirmed this clinical classification and located the murmurs either in mid-systole or late systole; it also showed the absence in such cases of auricular systolic and diastolic murmurs. In patients with mitral stenosis the phonocardiograph showed that the murmur which presented clinically as a systolic murmur usually started during the P-R period of the electrocardiogram, that is, during auricular systole, as did the presystolic murmur. Even in the few exceptions where the murmur was later and coincided with the start of ventricular systole, the term "mitral incompetence" would have been incomplete as in each there was a mid-diastolic murmur giving proof of mitral stenosis. The common incidence of a mid-diastolic murmur immediately succeeding the third heart sound in mitral disease, for it was found in each of 74 cases, stimulates the clinical search for this murmur in patients suspected of the condition. Should future investigation show that this is an invariable graphic finding in mitral disease it will prove to be a physical sign of inestimable value.—Evan, British Heart Journal, October, 1947.

Special Article

REPORT OF THE MEDICAL MISSION TO PUERTO RICO AND TO THE VIRGIN ISLANDS

ERNEST E. IRONS, M.D.
Chicago

In May 1947 the Secretary of the Interior requested several members of the American Medical Association to consult with him about what measures might be taken to improve the medical care of the indigent in certain portions of the United States and outlying regions. At this conference, which included the Executive Committee of the Board of Trustees of the American Medical Association, Dr. Morris Fishbein and Dr. George Lull, the Secretary of the Interior, Mr. J. A. Krug, requested this group to organize medical missions to include those to Alaska and to Puerto Rico and the Virgin Islands. Dr. W. A. Morgan, attached to the office of the Secretary of the Interior, was made the secretary of this group and accompanied the mission to Puerto Rico and the Virgin Islands.

The mission to Puerto Rico and the Virgin Islands as organized included:

Dr. W. L. Benedict, Chief of the Eye Department, Mayo Clinic.

Dr. E. E. Irons, Internal Medicine, University of Illinois.

Dr. James McLester, Nutrition, Birmingham, Ala.

Dr. E. C. Person, Surgery, Cornell University, New York.

Dr. H. N. Sanford, Pediatrics, Presbyterian Hospital, and University of Illinois, Chicago.

Dr. G. M. Saunders, Epidemiology, Washington University, St. Louis.

Dr. John H. Willard, Gastrointestinal Diseases, University of Pennsylvania.

Dr. John Youmans, Dean of the University of Illinois, Tuberculosis and Nutrition.

Miss Edna Newman, Director of Cook County Hospital School of Nursing, Chicago.

Members of the mission saw many patients, including those suffering from surgical, medical and ophthalmologic difficulties.

Part of the commission reached San Juan, Puerto Rico, from New York on January 20, other members arrived a few hours later from Miami, Fla. We were met by officials of the health department, and as soon as the real intent of the commission was understood full cooperation was received from physicians and other officials. We at once conferred with Dr. Juan A. Pons and laid out a program of visits to various institutions by the members of the commission. In a number of instances the same institution was visited by two or three members, but it seemed important for each member of the commission to come in personal contact with as many physicians as possible. Dr. Morgan and I went to call on Governor Pinero. We got in touch with Acting Governor de Castro at

St. Thomas, Virgin Islands, and went by plane on January 23 to St. Thomas to arrange for appointments for all the members of the commission.

Contacts with the physicians of Puerto Rico were arranged for by means of round table conferences, a limited number of lectures and by arranging daily schedules for each member of the commission to visit hospitals and observe their general working and how they fulfilled the special functions in which the member of the commission was interested. On a number of occasions we met with larger numbers of physicians. We believed that the intent of the Secretary of the Interior probably could be best carried out by a combination of observations concerning medical conditions in practice and in hospitals and by the observation and examination of a limited number of patients in consultation with the physicians. For example, Dr. Benedict saw many patients with eye diseases in several hospitals in Puerto Rico and also those in St. Thomas and St. Croix, Virgin Islands; other members saw a number of medical and surgical conditions in which our advice was asked. From the reactions of the Puerto Rican and Virgin Island physicians, it is believed that the visit will encourage them and stimulate a better quality of medical service.

MEDICINE, ECONOMICS AND NUTRITION

The health of people is closely connected with their economics and nutrition. This is especially true of Puerto Rico and the Virgin Islands because in both groups there is a chronic condition of undernutrition; in fact, the greatest single factor in the health of the people of Puerto Rico is that of nutrition. The total food supply, including what is raised locally and what is imported with funds derived from sugar, is not adequately sufficient to feed the population. The only food not imported is sugar. Some improvement of the total diet of the people is being accomplished by educational methods in the use and preservation of foods and the use of fruits such as guavas and mangoes, which are available in season but often go to waste. Even with these comparatively minor dietary improvements, the total food supply available for Puerto Rico based on local production and present economy is becoming more inadequate. This is because the over-all economy of Puerto Rico is inadequate to support the rapidly increasing population. Figures based on death rates and birth rates indicate that with a population of something over 2,000,000 (620 per square mile in an agricultural community), the net population of Puerto Rico increases by 1 every eight minutes, or 65,000 every year.

Government expenditures by military personnel during the war temporarily improved the economic situation. This seems to have been reflected in a reduction of the death rate from 20 in 1937 to 13 in 1947. Another method of improving the economics has been suggested in the development of a tourist economy. Until recently the almost complete absence of hotel accommodations for winter tourists has prevented the use of a very pleasant climate to produce revenue from tourists. If the present definite increase in hotel accommodations could be augmented to a greater extent, a decided increase in revenue would result, particularly in and about San Juan.

Measures are being taken to increase the use of locally caught fish by the population, which would seem possible with the development of refrigeration systems.

EMIGRATION

Years ago a considerable number of Puerto Ricans were taken to the Southwest region of the continental United States. A similar attempt to move some Puerto Ricans to Hawaii was not especially successful. It is now suggested that emigration to South America and to Central America be considered. Some such programs might be partially successful; assuming that it would work, the removal of over 50,000 Puerto Ricans a year would be necessary to hold the population of Puerto Rico at its present level.

INCREASE IN INDUSTRIALIZATION

Progress has been made in establishing industries in Puerto Rico. The glass bottle and paper carton factories and the cement plant are examples, but such development as is possible cannot take care of more than a fraction of the increasing population. In the past certain industries have been established only to fail by reason of strikes fomented by labor leaders from the United States. The Wage and Hour law passed some years ago, with the best intentions as far as continental United States was concerned, interfered greatly with the needlework industry in Puerto Rico. Although this law was intended to help the underprivileged, it resulted in the accentuation of economic problems in many Puerto Rican families without correcting the difficulties.

EDUCATION

There are estimated to be 540,000 illiterate persons 5 years of age and over. In Puerto Rico the educational program is handicapped by the difficulty in getting qualified teachers. The original educational program which provided for English as the teaching language has now been modified so that English is one of the subjects taught and is not the language of teaching, especially in the lower grades. Many of the teachers have had limited educational preparation.

BIRTH CONTROL

In 1937 the transmission of information on birth control was legalized by the Puerto Rican Supreme Court, has limited such information to cases in which there are medical questions of health involved.

Now in 1948, there are twenty-seven birth control clinics but they have thus far had no demonstrable effect on the birth rate. The net reproduction index in Puerto Rico is 1.7, the highest in the world. In Belgium with the population density of 700 per square mile, the net reproduction rate is 0.75. The life expectancy in Puerto Rico in 1940 was 45 years.

MEDICAL SERVICE

There are about eight hundred physicians in Puerto Rico, at least two hundred of whom are in and around San Juan; rural districts are poorly supplied. This situation was accentuated during the war as it was in continental United States. It was reported that seventeen municipalities were without physicians. It is said that some sixty-four physicians were brought in from Cuba and Santo Domingo with the understanding that they should have temporary licenses only. The average performance of these physicians was far below standard. Most of these imported physicians did not go where they were expected to go. This importation also has been a source of irritation between the Puerto Rican Medical Association and the Insular Department of Health. This practice has been discontinued, and it is to be hoped that it will not be resumed; otherwise, standards of medical service in Puerto Rico will be lowered rather than raised.

A large proportion of physicians on the staffs of municipal and district hospitals are on a salary averaging from $300 to $450 per month. Many of these men give adequate service for value received; many more give service of poor quality. It is easy to understand how a physician in a municipal hospital, where he has nothing to work with and no encouragement, will deteriorate even though he receives a relatively good salary. Undoubtedly there will be improvement in many municipal hospitals when the standards of operation of the health centers become established. One solution of this question of service in municipal hospitals would be to place the responsibility for operation under the direction of the Insular Commissioner of Health. Such a change probably would be opposed by local political influence. The Commissioner of Health has a plan for rotating the rural physicians into the district hospitals. This would improve the performance of the physicians in rural communities.

RURAL COMMUNITIES

Members of the large strictly rural population between the towns must look to adjacent municipalities for such medical attention as they get. They have little transportation and no funds to pay for such as is available. In many of these regions there seems to be no possibility that a physician could make a living because of the extreme poverty of the people; the only alternative seems to be that of improving the care given through public health measures. Much has already been done to reduce the incidence of malaria and hookworm.

To carry health activities to rural communities, there have been set up fifty-five type A units (building, equipment and personnel) which operate sixty-five rural health units. In addition there are twenty-one type B, or purely public health, units. Many of these are associated with milk stations. Adequate supervision of those units is not available. In some which I saw in operation, the quality of service was extremely poor. In the past year an effort has been made to extend the training of personnel through scholarships, in service institutions, short courses, seminars, conferences and the like for the positions as nurses, sanitary engineers, sanitary inspectors, medical social workers, clerical personnel, physicians, public health aids, nurse-midwives, x-ray technicians, milk station aids and others.

HOSPITALS IN PUERTO RICO

District Hospitals—Five district hospitals operate in Puerto Rico: two others are planned, all under control of the insular government. Their operation has been vastly improved by the efforts of Dr. Juan A. Pons, who was made commissioner of health of the island about 18 months ago. The quality of work at the Bayamon District Hospital is excellent so that I believe most members of our commission felt that it justified approval of this hospital for intern and residency training. Next in order of excellence is the hospital at Arecibo. That at Fajardo at the eastern end of the island is well appointed but seems to lack personnel and internal harmony. It has been reorganized for a shorter time, and this may account for the deficiencies noted. The hospital at Aguadilla is not as well advanced in regard to organization as the others. Lack of personnel is the chief difficulty. The district hospital at Ponce is not well operated. On the whole, however, there has been an enormous improvement in the last two years in the operation of these hospitals and they are a credit to those charged with medical care in the island.

Municipal Hospitals.—The municipal hospital at San Juan is doing excellent work. The municipal hospital at Arragua, which I did not see, is said to be doing good work. In the remaining municipal hospitals in various towns the conditions of the hospitals and the kind of work done in them is not creditable. Apparently the difficulty is largely due to the political domination of hospital operation and the employment of physicians who have poor ideals or no ideals at all. Almost without exception there is an air of hopelessness and lethargy. In some hospitals the beds were dirty. Records were almost nonexistent. It is possible that in time the standards demonstrated in the district hospitals and in the smaller health centers may stimulate better work in the municipal hospitals. A much more important change would be to place the operation of municipal hospitals under the insular government. At present most municipal hospitals are as much a discredit as the district hospitals are a credit. This unfavorable opinion of municipal hospitals is supported by the comment on other municipal activities by the Commissioner of Health of Puerto Rico in his annual report 1946-1947, page 39.

OTHER HOSPITALS

There are two large hospitals for tuberculosis at Rio Piedras and a new hospital planned at Cayey. The hospital for the insane at Rio Piedras has accommodations for about 800 persons, but there are 1,400 patients. Dr. Fernandez-Marina, who has been in charge here only six months, received three years of preliminary training in St. Elizabeth's Hospital, Washington, D. C. He is doing good work under great difficulties. It is understood that plans are under way for the enlargement of this institution.

LEPER COLONY

There are 32 patients at the leper colony; in addition, 11 are on parole. This number of cases is said to represent about 10 per cent of the total cases on the island.

PRIVATE HOSPITALS

The Presbyterian Hospital at San Juan has one hundred and ten beds, is well run and has been a training ground for improvement of medical practice in Puerto Rico. St. Luke's hospital at Ponce has eighty-six beds, also the Pila Clinic has three hundred beds and does excellent work. A special hospital for the treatment of cancer in Santurce has seventy beds. Most of the patients here treated are indigent. There are a number of private clinics, sometimes with a small number of beds attached, in which those able to pay are treated. The vast majority of persons, however, are treated in public instutions.

HEALTH CENTERS

The new health center at Rio Grande has facilities for a dispensary, a milk station and a few beds for the local care of patients who do not require transfer to a large hospital. Fourteen such health centers are planned over the island under the direction of the insular government. It is understood that the funds are available and that in most instances the contracts for construction have been let.

MEDICAL EDUCATION

A survey made three years ago by Dr. Victor Johnson representing the Council on Medical Education of the American Medical Association suggested that if a medical school is established it should be established somewhere in the metropolitan area of San Juan-Rio Piedras. Shortly after this survey an act was passed by the Puerto Rican legislature authorizing the establishment of a medical school in Ponce. This law was vetoed by the governor on the ground that the provisions of the law were not well founded. It is understood that any establishment of a medical school has now been postponed. In the meantime, to afford needed medical education, some fifty scholarships have been established whereby Puerto Rican students may obtain medical education in the United States. There are about one hundred and ten such students now studying in medical schools in the United States and about fifty more supported by private funds. A difficulty has developed in that, with the pressure on the medical schools of the United States to receive veteran students, the number of places available for Puerto Ricans has been further limited. If places for fifty Puerto Rican students per year can be secured in the medical schools of the United States, the physician needs of Puerto Rico will ultimately be met.

The establishment of a satisfactory four year medical course in Puerto Rico would involve questions of standards in the basic sciences of the first two years which would be difficult to attain at present. Furthermore, the operation of a medical school for the first two, or basic science, years is expensive, and as yet there do not seem to be sufficient men available for the satisfactory conduct of the last two, or clinical years. This situation may change with the improvement in quality of service in the district hospitals.

PRACTICANTES

In addition to the physicians said to have medical training in Puerto Rico, there is another group of "practicantes." Many of these have acted as male nurses and gradually have expanded their activities so that at present there are about one hundred licensed male nurses and about one hundred licensed "practicantes," who attempt minor medical procedures. They also speak of themselves as minor surgeons and regard themselves as a distinctly professional class. Many of their performances are regarded as injurious to the persons on whom they work. In 1945 the legislature of Puerto Rico legalized the practice of "practicantes."

The unfortunate effect of such a law will be to impose on the poorest inhabitants the worst type of medical service.

GRADUATE MEDICAL STUDY

The education of a physician has only begun when he receives his diploma in medicine. Further progress depends on his own efforts to learn and on the facilities afforded him to improve his knowledge of medicine. This educational process can be carried on in formal school or in his daily practice in hospitals, provided these hospitals are properly operated. A teaching program in a hospital is a large factor in improving the quality of care given to patients in that hospital. The School of Tropical Medicine and the several bureaus of the insular government of health and hospitals afford training grounds for the development of better physicians.

THE SCHOOL OF TROPICAL MEDICINE

The School of Tropical Medicine, a graduate school, was organized under an Enabling Act passed in 1928 which provides for a joint effort between the University of Puerto Rico the insular government and Columbia University, New York. Within this past year Columbia University found it necessary for budgetary reasons to discontinue its contribution of $30,000 a year, and it was at first feared that Columbia would be forced to withdraw from the school. Arrangements have now been made whereby Columbia retains the same position under the Enabling Act as it did before but is obligated to pay only the salary of the director of the school. Present plans look toward the enlistment of interest from other American universities, which will be offered the opportunity to join in the program through Columbia University. Dr. H.W. Brown of Columbia is at present making a study of the possibilities for research at the School of Tropical Medicine. Considerable research is now going on at the school. An outline of the possibilities for research will be formulated by Dr. Brown and distributed to various universities which may wish to send students to avail themselves of the educational opportunity afforded.

The School of Tropical Medicine has been, in my opinion, the greatest single factor in improving educational standards in medicine in Puerto Rico. Many of the men now occupying important and educational positions in medical life of Puerto Rico date their educational progress from the stimulation received from study and residence in the School of Tropical Medicine. Columbia University also has availed itself of the opportunity for resident study by members of its faculty. Significant work has been done on diseases current in Puerto Rico such as sprue, filariasis, schistosomiasis and diseases arising from nutritional deficiencies. The School of Tropical Medicine remains the strongest single element for improvement of medicine in Puerto Rico. The present director is Dr. Morales Otero. The school operates a school of public health for the training of technicians and offers graduate training for physicians in public health. It operates a dispensary with about 20,000 patients a year. These are indigent patients who are referred by the mayors of the several municipalities who certify to their indigency.

SUMMARY OF MEDICAL CARE

The quality of medical care of the people of Puerto Rico has been greatly improved in the last ten years. Sanitation has been improved through the educational and engineering measures instituted by the Rockefeller Institute, the insular government and, more recently, by the Army and Navy medical corps. Medical care in governmental hospitals has been marvelously improved as far as four of the district hospitals and the municipal hospital in San Juan are concerned. The establishment of health centers similar to that at Rio Grande, of which ultimately there will be fourteen, will carry this improvement in medical care a step further out into the rural areas. The setting up of milk stations throughout the rural districts also has helped in the education of the populace in better methods of caring for themselves.

Against this very creditable improvement, there is the lamentable quality of care given in most of the municipal hospitals and the extremely sketchy medical care received by the inhabitants, particularly in rural districts. The quality of this care cannot be improved by the introduction of badly trained and ignorant physicians, especially those whom the governments of surrounding countries, whose own medical care needs improvement, are willing to export to Puerto Rico. While the quality of medical education and medical care in Puerto Rico is improving, more could be done with present personnel if some of the physicians now receiving relatively good salary were induced to give a day's work for a day's pay.

THE VIRGIN ISLANDS

Medical care of the indigent in the Virgin Islands, St. Thomas, St. Croix and St. John, is also closely connected with the economics and nutrition of the people. The population of St. Thomas is estimated as 16,000 to 18,000; that of St. Croix, 12,000; that of St. John, a few hundred. Agricultural possibilities in St. Thomas are slight; those of St. Croix are somewhat better, although the fertility of the land of St. Croix for the growing of sugar cane is inferior to that of Puerto Rico.

During the war the construction program of the Navy and the expenditure of funds by Navy personnel relieved the economic situation. Possibly the best answer for St. Thomas and in part for St. Croix would be a tourist economy. This would probably be proportionately more effective than a similar program in Puerto Rico.

One difficulty arises through the longstanding attitude of government toward the people. The Danes, who received the Virgin Islands as a present from the British in 1679, wished from the beginning to maintain the favor of the inhabitants, and when it was recognized that the children of the indigent needed help, milk was given away. After our Navy took over this free care was extended, but some persons who had a relatively good income also insisted on free milk and then free prescriptions; thus governmental care has increased progressively. It is obviously difficult to administer free care and free food and at the same time to maintain any sense of responsibility in the individual. The situation in St. Thomas is an

EDITORIAL ANNOUNCEMENT

The absence of the compositors employed by the American Medical Association from their work continues. This issue of THE JOURNAL has been prepared largely by the use of Vari-Typer machines. Because of the difficulties of reorganization of the headquarters office necessitated by this situation, the editorial material in this issue of THE JOURNAL has been greatly condensed.

WHAT IS OSTEOPATHY?

In 1939 THE JOURNAL called attention to a case[1] in which the Supreme Court of Kansas entered a judgment ousting an osteopath from the practice of medicine and surgery and decreeing that his license to practice osteopathy permitted him to practice manipulative surgery but that he was not licensed or authorized to prescribe or administer drugs as remedial aids. The Kansas court said that the phrase in the osteopathic act which authorized persons licensed under it to practice osteopathy "as taught and practiced in legally incorporated colleges of osteopathy in good repute" could be construed only in this way. The court said further that if osteopathy had abandoned its fundamental opposition to drug therapy and operative surgery, as of the date of the enactment of the act, 1913, that fact never had been recognized by the legislature of the state of Kansas. The court next said that the statutes of Kansas recognized the "practice of osteopathy" and the "practice of medicine and surgery" as separate and distinct and that the use of drugs as remedial aids and the use of operative surgery did not, in 1913, form a part of osteopathy.

Both prior to the Kansas decision and since it was rendered the courts have without significant exception limited osteopaths, who are licensed as such, to the field in which they profess to specialize and in which they assert competency; legally osteopathy is a field of healing without the use of drugs and without operative surgery. The Kansas decision was of special importance because the osteopathic acts of several other states contain phraseology similar to that construed by the Kansas court. Apparently osteopaths had interpreted such laws as authorizing them to utilize any modality about which any instruction was given, however meager, in any "legally incorporated college of osteopathy of good repute," in any place at any time. Such an interpretation, if correct, would have provided a simple way of expanding the scope of osteopathic practice.

Even after the decision in the Kansas case, some osteopaths continued to invade the field of medicine and surgery and four successful injunction suits were filed to prevent this invasion. Not only have osteopaths in Kansas sought to practice medicine and surgery but also optometry. Here again the state Supreme Court told them to confine their practice to osteopathy.

Still insistent that their own construction of the Kansas laws prevail over that of the Supreme Court of Kansas, a number of osteopaths, including the four against whom injunctions have been issued, have recently joined in filing before a three judge federal court a complaint against the Governor and the Attorney General to restrain them from enforcing the section of the osteopathic act dealing with scope of practice, as construed by the state Supreme Court, on the ground that that section, as construed, is discriminatory and violative of their rights under the Constitution of the United States. An appeal lies direct to the U. S. Supreme Court from the decision of the three judge court, whatever that decision may be. Evidence in this case is scheduled to be heard beginning April 19.

The issues involved in this case are of tremendous significance not only to the state of Kansas and to those states with similar osteopathic laws, but possibly to all states. The final determination by the U. S. Supreme Court, it has been indicated, may well affect licensure laws generally. If the Supreme Court overrules the Supreme Court of Kansas, it will be entering into the control of medical practice. Then the osteopaths, without meeting the requirements all others must meet to obtain the right to practice medicine and surgery from the state legislature and from the state Supreme Court, would have a mandate from the U. S. Supreme Court granting them that right. The issue is worthy the attention of all who wish to protect the rights of individual states to control the practice of medicine within their own borders and also all who wish to maintain a high standard of medical practice in our nation.

REGISTRATION OF CAUSES OF DEATH

State and federal vital statistics offices often experience difficulty in obtaining accurate information on death certificates. The Registrar of Vital Statistics, summarizing a recent study of death certificates filed in one state, notes that half of all the certificates filed were found to be defective in regard to medical certification of cause of death.

The types of defects were classified into three categories: obsolete or unacceptable terminology, incomplete reporting and inaccurate reporting. Obsolete or unacceptable terminology includes diseases reported under nondescriptive names when descriptive names are available, vague and ambiguous terms such as senility, stillbirth and heart failure. Incomplete reporting means the omission of one or more of the following items: type of organism, anatomic site, duration of illness and underlying causes. About half of all defects classed as incomplete reporting are due to the omission of underlying causes of the immediate cause of death. Inaccurate reporting involves confusion between direct and contributing causes, improbable cause order or improbable duration. The omission of underlying causes was the most frequent defect of this type.

The study compared the reporting in rural areas with that in the large metropolitan area located in the state. Both metropolitan and rural physicians filed certificates with about the same number of defects. A special anaylsis of over 100,000 death certificates suggested that a certain portion of the practicing physicians are responsible for a large share of the defective certificates.

These defects present a serious problem to all agencies that use vital statistics, particularly in view of the expected new "International List of Diseases and Causes of Death." The present plan is to classify all deaths by the underlying cause, abandoning the use of the "Manual of Joint Causes of Death." Physicians should become acquainted with latest rules concerning death certification if research in the field of vital statistics is to be successful.

TRANSMISSION OF EPIDEMIC GASTROENTERITIS TO HUMAN VOLUNTEERS

In the summer and fall of 1946 outbreaks of acute gastroenteritis appear to have spread from hospitals in New York to state mental hospitals and prisons.[1] During the next winter sizable outbreaks occurred in fifteen state institutions. In one institution the first cases were noted on December 16 and in about a month 589 cases with 7 deaths were observed in 2,623 inmates and 115 of 354 employees. The spread in this and other institutions was not apparently related to water, food or milk supply and seemed best explained by person to person infection. There are indications that the general population of upstate New York was also affected. The onset was sudden, with profuse, watery diarrhea, frequently with vomiting, usually without fever, the acute stage lasting on the average three days. Thorough examinations by bacteriologic and morphologic methods did not explain the causation of the disease, but in human volunteers, men 21 to 25 years of age, typical cases followed the oral administration of bacteriologically sterile fecal filtrates from patients with the natural disease.[1] The incubation of the experimental disease ranged from one to five days, with a mean of three days. Unfiltered washings from the throats of patients with the experimental disease likewise caused acute gastroenteritis in volunteers. Inhalations by volunteers of throat washings from patients with epidemic as well as experimental infections gave negative results. There seems to be no good reason to question the claim that acute gastroenteritis was transmitted to human volunteers. The experiments were made with completely adequate controls on all sides under the auspices of the New York Board of Health in Albany. The demonstration that the causative agent in the form of acute gastroenteritis here described is present in fecal filtrates of patients is an advance of fundamental importance in the study of such infections. Identification of the causative agent in question awaits further success in such study.

Cancer Drive Launched in Constitution Hall

Dr. Morris Fishbein, Editor of THE JOURNAL, was one of several speakers who helped stars of radio and screen launch the annual cancer drive in famed Constitution Hall. On the speakers program with him were: Dr. Vannevar Bush, president of Carnegie Institute and chairman of the Research and Development Board of the National Military Establishment; House Speaker Joseph Martin; Federal Security Administrator Oscar R. Ewing; Douglas Poteat, executive vice president, American Cancer Society, and others. Dennis Day, singer on the Jack Benny program, brought his radio show, "A Day in the Life of Dennis Day," and was master of ceremonies on a program with Nancy Carroll, Ruth Chatterton and other theatrical luminaries.

Entry Into World Health Organization Delayed

Legislation that would make the United States a member of the World Health Organization was killed by a 5 to 2 vote of the House Rules Committee which had tabled the bill without explanation several weeks ago. Republican leaders who would not permit use of their names said that they opposed the bill because they considered it the opening wedge in an effort to have the United States pay medical bills of the entire world. A G.O.P. leader told newsmen: "The bill is dead and it is going to stay dead. The word to that effect has gone out and it will stick." Recently, Dr. Edward L. Bortz, President of the American Medical Association, has stressed the importance to this country of joining the World Health Organization. The Soviet Union joined last week, and only France and the United States are lacking of the twenty-six members of the United Nations needed to bring the constitution of the W.H.O. into effect.

Dr. Bortz declared that when this country does join, the United States and not the Soviet Union will become the dominant member. He stated: "I doubt very much whether the World Health Organization could succeed without the United States. The world needs our knowledge of nutrition, preventive medicine and sanitation, and we need the research results of scientists in other nations. Medical science knows no boundaries.

Nation Urged to Match Total War With Total Medicine

Col. Edgar Erskine Hume, U.S.Army, president of the Association of Military Surgeons of the United States, declared in his address as Kober Lecturer at the Georgetown University Medical School: 'We must mobilize our entire resources of preventative medicine and hygiene. All too often, our warfare against disease is defensive only.'' In other words, he proposed that total war calls for total medicine. Colonel Hume described war as the most terrible of all diseases, yet pointed out that medicine traced its advances through the "stimulus" of past wars. He remarked that the atomic bomb may not prove to be wholly a destructive weapon, as use of radioactive isotopes, byproducts of the manufacture of the atomic bomb, may produce epochal medical advances.

Health Institute Seeks Bethesda Site For New Center

The National Health Institute is negotiating for the purchase of 311 acres of land in Bethesda, Md., as the site of the proposed $40,000,000 medical research center, it was reported here. A Senate Appropriations Subcommittee was asked for a direct $5,000,000 appropriation to start construction this summer, with a contract authorization for another $25,630.000. The new research center would have five hundred beds and be devoted completely to the study of heart disease, cancer and other diseases. The completion date is tentatively set for July 1, 1951. Dr. R. E. Dyer, head of the institute, revealed that the government has already acquired 140 acres of land.

Additional Funds Recommended For Atomic Energy Commission

The House Appropriations Committee has endorsed increased programs of atomic energy research and has recommended that an additional $150,000,000 be added to contract authority for the Atomic Energy Commission. This extra amount was included in a $3,000,000,000 deficiency bill to make up deficits of various federal agencies. A total of $659,091,863 is now included in the commission's new contract authority. The House group urged the commission to "move forward with all possible speed in its research programs, both in the wartime and peacetime uses of the newly discovered secrets." Chairman David E. Lilienthal stated during hearings: "We have to assume, in the desperate state the the world is in, that it is our job to push ahead as fast as possible, not knowing how much time there is left."

Advocates School Health And Transportation Benefits

Senator Brien McMahon Democrat, of Connecticut, has introduced an amendment to the $300,000,000 federal aid to education bill which would extend school health and transportation benefits to all parochial and other tax-exempt, nonpublic schools. He proposed that a new title be added to the measure allocating $5,000,000 for nonpublic schools for purposes permitted under the constitution. He pointed out that under Supreme Court decisions, these are interpreted to be limited to transportation of pupils, school health examinations and related school health services and purchase of nonreligious instructional supplies and equipment

Thirty Washington Children Undergo Treatment for Mental Retardment

Officials of the Children's Hospital Welfare Clinic in Washington, D. C., reported that thirty children are receiving regular doses of glutamic acid, described as a new drug reportedly used in a previous mass test at Columbia University to aid mentally retarded children. Most of the children receiving treatment in the test here are much younger than the group in New York, where teenage subjects were said to have responded favorably.

Medical Legislation

STATE LEGISLATION

Arizona

Bill Enacted. —H.4-XXXXX has become chapter 33 of the Laws of 1948. It enacts an Arizona hospital survey and construction act for the purpose of conducting a survey of existing hospital facilities and a construction program for the building of additional needed facilities. The law provides for the appointment of an advisory survey and construction council, one member of whom shall be chosen from a panel of four submitted by the Arizona medical association and another member of whom shall be chosen from a panel of four submitted by the Arizona society of osteopathic physicians and surgeons.

Kentucky

Bill Enacted—S.158 was approved March 25. It creates a board of examiners for chiropody and defines chiropody as the diagnosis and the local, medical, mechanical and surgical treatment of ailments of the human foot, and massage in connection therewith, except amputation of the foot or toes, or the use of anesthetics other than local, or the use of drugs or medicine other than local.

S.342 was approved March 25. It creates a Kentucky Building Commission to have charge of buildings constructed throughout the state and provides that appropriations to this commission shall be used, among other things, for matching funds for hospital construction under any law now existing or that may be passed by the national congress.

Mississippi

Bill Enacted—H.386 was approved March 23. It provides for the appropriation of $510,000 to the state medical education board for the purpose of carrying out the provisions of the law relating to medical scholarships and loans

Bill Enacted—H.717 was approved March 23. It provides for the appropriation of $300,000 to defray the expenses of the state program of eradication and control of syphilis and other venereal diseases.

New York

Bill Enacted.—CCH A. Res 161 was adopted March 8. It continues the special joint legislative committee making a survey and study of the social, educational and physical problems of persons afflicted with cerebral palsy.

Bill Enacted. —S 1308 has become chapter 361 of the Laws of 1948. It amends the education law by repealing the existing definition of podiatry and enacting a definition as follows: A person practices podiatry who holds himself out as being able to diagnose ailments of the human feet by mechanical chemical and physical means and or as being able to practice minor surgery upon the feet within the following limitations· the practice of minor surgery shall not permit operations upon the bones, muscles or tendons of the feet or any other part of the body except operations for minor deformities of mechanical and functional nature, including the structures superficial to the deep fascia and including all structures of the terminal phalanges. It shall confer the right to treat for disease, pain, injury and deformity of the feet and it shall not include any other part of the human body. The treatment of fractures shall be limited to simple uncomplicated fractures of the phalanges and metatarsals The use of anesthesia shall be limited to local anesthetics for therapeutic purposes as well as for anesthesia, and the right to use nonnarcotic postoperative sedatives.

Virginia

Bills Passed.—H. 439 passed the senate March 11. It proposes to require every practicing medical doctor to obtain a revenue license. S. 106 passed the house March 13. To amend the medical practice act, it proposes to authorize the state board of medical examiners to suspend or revoke the certificate of a physician who has been the legally responsible head of a hospital the license of which has been revoked because of illegal practice or conduct or practices detrimental to the welfare of a patient therein by the state board of health. S. 107 passed the house March 13. It proposes to require the annual renewal of certificates to practice medicine, homeopathy, osteopathy, chiropractic naturopathy or chiropody on or before June 30 of each year

Bills Enacted.—H. J. R. 41 was adopted March 13 It directs the Virginia advisory legislative council to make a thorough study of the methods and practices of corporations and associations engaged in furnishing hospital and medical service on the prepayment plan. H. 354 has become chapter 205 of the Laws of 1947. It makes it unlawful for physician dentist or optometrist to practice his profession as a lessee of any commercial or mercantile establishment or to advertise, either in person or through any commercial or mercantile establishment, that he is a duly registered practitioner and is practicing or will practice medicine, dentistry or optometry as a lessee of any such commercial or mercantile establishment. H. 412 has become chapter 244 of the Laws of 1948. It amends the law relating to occupational diseases by including pneumoconiosis within the list of occupational diseases covered by the act. S. J. R. 27 was adopted March 11. It creates a committee to study medical education in general in the state and the relation of medical education to the services that it renders to the people. S 105 has become chapter 68 of the Laws of 1948. To amend the medical practice act, it proposes, among other things, to exempt therefrom interns and residents in legally established and licensed hospitals provided their practice is confined strictly to persons who are bona fide patients within the hospital or who receive treatment and advice in an organized outpatient department of the hospital to which ambulant patients regularly come for professional services rendered under the supervision of licensed members of the hospital staff. Such interns and residents, however, must have completed successfully the preliminary academic education required for admission to examinations given by the board in their particular field of practice or hold a valid license issued in a state maintaining standards acceptable for reciprocity with the state of Virginia. No graduate of a substandard medical school may be so employed except under particular circumstances.

Medical School To Televise

Northwestern University Medical School will use television to bring to the physicians and surgeons attending the annual session of the American Medical Association in Chicago, June 21-25, five days of programs showing both surgical procedures and clinical demonstrations. A committee composed of Drs. Walter Carroll, Stuart Abel and Henry E. Wilson Jr., all of Northwestern's medical faculty, announced that the week-long television program is the first of such magnitude utilizing video methods in medical education at the convention level.

Dr. Carroll said that among the surgical procedures to be televised will be obstetric and gynecologic procedures, including a cesarian section; the "blue baby" operation; early skin grafting in severe burns; gastric resection; surgery of the hand, and surgery of the chest. In addition, the video camera will reproduce a wide range of clinical material in the fields of internal medicine, orthopedics, cancer, dermatology, endocrinology and neurology.

A clinical demonstration concerning peripheral neural injuries will be conducted by Dr. Loyal Davis, chairman, department of surgery at Northwestern, and Dr. Lewis J. Pollock, chairman, department of nervous and mental diseases.

It is planned to broadcast the medical programs from 9 a.m. to noon and from 1 to 4 p.m. on each of the five days. The surgical procedures will be performed in two operating rooms of Passavant Hospital and the clinical demonstrations in adjoining classrooms. About fifteen hundred observers may witness a procedure simultaneously, six hundred in the Sheraton Hotel five hundred on the Navy Pier and four hundred at the medical school. It is estimated that about twenty-five physicians may see a program before each of the smaller screens, while the larger will accomodate about fifty. A television screen measuring 8 by 10 feet (244 by 305 cm.) now is being manufactured and has been promised to Northwestern for the convention period. This screen would accomodate an additional audience numbering in the hundreds.

GOVERNMENT SERVICES

AIR FORCE

DDT DUSTING DURING CHOLERA EPIDEMIC

Two C-47 transport planes equipped with DDT spray tanks flew a total of two hundred and six missions against cholera-carrying flies and malaria-carrying mosquitoes in Egypt, the Mediterranean theater and Germany during 1947. The Air Surgeon's Office, U. S. Army Headquarters in Europe, reports that from October 16, when they answered an emergency request through the United Nations' World Health Organization to help check the cholera epidemic in Egypt, until December 10 the C-47s flew a hundred and ten sorties over the cholera-affected districts of Cairo, Alexandria and neighboring villages.

During two months of serial spraying in Egypt, the transports, equipped with four 200 gallon tanks capable of saturating an area of 1 square mile with the spray in four minutes, sprayed 560,000 pounds of the DDT spray. Members of the two crews who worked seven days a week for two months in Egypt on spraying missions have all been commended by Lieut. Gen. Curtis E. LeMay, USAFE Commander. The DDT spraying, combined with other emergency measures put into effect by Egyptian health officials, turned the tide in combating the epidemic, which reached its peak October 25-27.

Last summer the USAFE planes flew ninety-six missions in the European Command and the Mediterranean theater, where the insect problem and the inaccessible low-flying terrain warranted the use of aerial spraying.

SPECIAL RESEARCH POSITION

The Air University School of Aviation Medicine, Randolph Field, Texas, is in receipt of an announcement from Headquarters Air Force, that the school has been allotted one of a limited number of special research positions authorized by Congress to attract outstanding scientists to service laboratories. The school of Aviation Medicine intends to utilize the new allocation, which carries with it a salary of $10,000 to $15,000 per annum, to establish a civilian position for a director of research. Inquiries concerning this vacancy should be addressed to the commandant.

NAVY

NEW REGULAR OFFICERS

The following naval medical officers have been cepted for transfer from the Naval Reserve to e Regular Navy: Lieut. (jg) John G. Esswein, New Provo, Utah; Lieut. (jg) John G. Esswein, New York; Lieut. (jg) John S. Neill, Valley Station, Ky., and Lieut. (jg) John M. Packard, Saranac Lake, N. Y.

The following physicians from civil life were recently commissioned lieutenants (jg) in the Medical Corps of the Regular Navy: Richard S. Clover Jr., Philadelphia; Clayton R. Entwistle, Philadelphia; Henry L. Hook, Newark, Ohio, and Arthur M. Tyson, Nashville, Ga.

The following physicians were recently transferred from the active Naval Reserve to the Medical Corps of the Regular Navy: Lieutenant Dominic A. Kuljis, of Bellingham, Wash., and Lieutenant (jg) Francis E. Hornbrook, of New Martinsville, W.Va. Comdr. Theodore E. Hoffman of Vassar, Mich., was recently transferred from the inactive Naval Reserve to the regular Navy Medical Corps.

The following physicians from civil life have been appointed to the Regular Navy Medical Corps as lieutenants (jg), temporary; George W. Kleinschmidt, Marietta, Texas; Norman B. Metcalf, Omaha; Frank Ostapowicz, Pittsburgh; Edward J. Rupnik, Library, Pa.; John G. Pifer, Pittsburgh; Carl M. Worley, Pittsburgh; William F. Harding, Pottsville, Pa.; Richard K. Loeffler, Rochester, N.Y.; Arthur R. Molar, Cincinnati; John H. Nickel, Warren, Ohio, and John R. Lee Jr., Brooklyn.

The following graduates of the Navy's V-12 program have been transferred to the Medical Corps of the Regular Navy in the grade of lieutenant (jg): George F. Sager, Portland, Maine; James T. Thorn, Vina, Ala.; and Theodore H. Wilson Jr., Catonville, Md.

Capt. Frank F. Wildebush (MC), Comdr. J. A. Forte Jr. and Lieut. (jg) B. H. Pender have recently accepted appointments in the regular Navy Medical Corps.

ENCEPHALITIS IN THE CAROLINE ISLANDS

A team from the Naval Medical Research Institute, Bethesda, Md., recently returned from the Caroline Islands, where for two months they investigated an outbreak of encephalitis among the natives of the island of Ponape. About twenty natives were affected by the disease each month during the visit of the research team to the island; no deaths have been reported. Engaged in the investigation were Comdr. Herbert S. Hurlburt (MSC), Union City, Pa., and Lieut. (jg) Charles A. Bailey (MCR), Rutherford, New Jersey.

PERSONALS

Dr. Edward L. Bortz, Philadelphia, President of the American Medical Association, was guest speaker at the Naval Medical Center, Bethesda, Md., February 27. Dr. Bortz' subject was "Medical Preparedness." Officers of the Army and Navy Medical Corps, Public Health Service and Veterans Administration and civilian physicians of the District of Columbia and adjacent counties were invited to attend. After the lecture refreshments were served, with the medical officers of the center acting as hosts.

Rear Admiral Joel T. Boone (MC) has been nominated for duty as general inspector of the Medical Department of the Navy. Admiral Boone, who is now on temporary duty as executive secretary of the Hawley Board, will succeed Rear Admiral Daniel Hunt, who will become inspector of medical activities on the Pacific Coast.

Lieut. Leona Jackson, educational director, Navy Nurse Corps, has returned from a tour of civilian institutions to which Navy nurses are assigned for instruction, including the universities of Colorado and Utah, the University Hospitals of Cleveland and the American Association of Nurse Anesthetists, Chicago.

VETERANS ADMINISTRATION

ADVISORY GROUP ACCEPTS REAPPOINTMENT

Carl R. Gray Jr., Administrator of Veterans Affairs, announces that all members of the Veterans Administration national advisory group on medical problems have accepted reappointment. They held a regular meeting in Washington, D.C., March 22. The group, appointed in compliance with Law 293, Seventy-Ninth Congress, acts in an advisory capacity to the administrator and to Dr. Paul B. Magnuson, chief of medicine and surgery, on policies concerning medical service to veterans. The following are members of the group: Drs. Charles F. McCuskey, Glendale, Calif.; John S. Voyles, St. Louis; Paul Titus, Pittsburgh; Guy W. Brugler, Boston; W.S. Middleton, Madison, Wis.; Francis J. Braceland, Rochester, Minn.; Claude C. Coleman, Richmond, Va.; Francis M. McKeever, Los Angeles; Derrick T. Vail, Chicago; A.R. Shands Jr., Wilmington, Del.; Dean M. Lierle, Iowa City; Roy Kracke, Birmingham, Ala.; A.C. Christie, Washington, D.C.; J. Stewart Rodman, Philadelphia; George F. Cahill, New York; William A. Hunt, Chicago; and Misses Eleanor Cockerill, Pittsburgh, Pa., and Katherine J. Densford, Minneapolis, Minn.

PROSTHETIC APPLIANCES

During the fiscal year ending last June 30, the Veterans Administration supplied disabled veterans with nearly 300,000 prosthetic appliances, including 8,000 artificial legs, 16,000 braces, 9,400 hearing devices, 32,000 pairs of eyeglasses, 17,000 pairs of arch supports and 157,000 stump socks for amputees.

CONTRACTS FOR HOSPITALS

The contract for the construction by the Veterans Administration of a two hundred bed hospital at Grand Island, Neb., has been awarded on a low competitive bid of $5,244,854.

The contract for the foundation and excavation work for the thousand bed veterans' hospital at Newark, N.J., has been awarded to the lowest bidder for $674,900. A few days ago the control for structural steel work on this hospital was awarded for $1,175,000. Bids for the general construction work will be invited in a short time.

Contracts for the main construction work on the 1,000 bed hospital at Buffalo, N.Y., have been awarded, the successful bid being $9,287,000 for the main building; the heating and ventilating contract was for $1,334,497 in addition, and the plumbing contract for $1,297,433.

The contract for the construction of a two hundred and fifty bed Veterans Administration hospital at Big Springs, Texas, has been awarded to the low bidder for $5,712,739.

The contract for the mechanical construction of the four hundred and fifty bed general hospital at Shreveport, La., has been awarded to the lowest bidder for $2,242,450.

Contracts have been let for the general construction, elevators and staff quarters for the two hundred and fifty bed veterans' general hospital at Iron Mountain, Mich., for $6,052,221.

The contract for construction of a three hundred bed hospital at Wilmington, Del. was awarded February 20, with a low bid of $6,911,000, the Army chief of engineers announced. A company was awarded the contract for the elevators for this hospital with a bid of $236,375.

The contract for the construction of the two hundred bed hospital at Beckley was awarded with a low bid of $4,975,123. The low bid for the contract for the elevators and dumb waiters was $161,513.

Contracts have been awarded for the general construction and installation of elevators for the two hundred bed Veterans Administration general hospital to be built at Altoona. The two contracts amount to $5,183,995.

PUBLIC HEALTH SERVICE

MENTAL HEALTH COUNCIL MEETING

The National Advisory Mental Health Council, which makes recommendations to the Surgeon General in the field of mental health, will hold its next meeting in Washington, May 14-15. Prior to this meeting, the three advisory committees to the council will meet: the Community Services Committee on March 8-9; the Training Committee on March 14-16 to consider applications for training grants, and the Research study Section on April 19-20 to consider applications for federal grants for research under the National Mental Health Council act. The chairman of the National Advisory Mental Health Council is Dr. Edward A. Strecker, University of Pennsylvania School of Medicine, Philadelphia; the chairman of the Community Services Committee is Dr. S. Alan Challman, Minneapolis, and the chairman of the Research Study Section is Dr. Nolan D. C. Lewis, director of the New York State Psychiatric Institute and Hospital, New York.

PERSONAL

Dr. John F. Mahoney, medical director, U. S. Public Health Service venereal disease research laboratory, Staten Island, N. Y., served as chairman at the recent meeting in Geneva, Switzerland, of the Expert Venereal Disease Committee of the World Health Organization Interim Commission. Dr. Mahoney is said to have been the first to demonstrate the effectiveness of penicillin against syphilis, for which contribution he received a Lasker Award through the American Public Health Association in 1946.

EFFECT OF WAR ON CHILDREN

A $20,000 research grant has been awarded to the International Committee on Mental Hygiene under the National Mental Health Act, Oscar R. Ewing, federal security administrator, has announced. The grant will be used to make a study of the effect of war on children. This study will be made under the direction of Dr. David Levy, professor of psychiatry, Columbia University, New York, and will be presented at the International Congress on Mental Health to be held in London, England, in August. The grant was recommended by the National Advisory Mental Health Council and was approved by the Surgeon General, U. S. Public Health Service.

EXAMINATION FOR PHARMACIST

The U. S. Public Health Service announces a written examination to be held June 21-23, 1948 for applicants for appointment in the regular corps in grades of junior assistant pharmacist, assistant pharmacist and senior assistant pharmacist.

Applicants must be citizens of the United States and graduates of a recognized school of pharmacy; applicants for the two higher grades must also have three and four years, respectively, of graduate professional training or experience.

The entrance pay for junior assistant with dependents is $3,391 a year, and for senior assistant pharmacist with dependents, $4,351.

Additional information may be obtained from the Surgeon General, U. S. Public Health Service, Washington 25, D. C., Attention: Division of Commissioned Officers.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

COLORADO

Postgraduate Courses.—The University of Colorado is offering course in nuclear energy in cooperation with the Denver County Medical Society, April 26-29. The course is limited to physicians. Among lecturers who will participate are Dr. Stafford Warren, dean, Medical School, University of California, Los Angeles; Col. Elbert DeCoursey, Brooke General Hospital, Ft. Sam Houston, Texas, and Capt. Lloyd R. Newhouser of the U. S. Navy. Inquiries should be made to the Office of Graduate Medical Education, University of Colorado School of Medicine, Denver. The registration fee is $8; there is no tuition.

The Colorado State Medical Society and the University of Colorado School of Medicine are collaborating in a course in medical public relations to be given in nine lectures during April and May for graduate and undergraduate medical students.

A course for physicians on supervision of the well child will be held at Colorado Medical Center, April 26-28. Dr. Lee Forrest Hill, past president, American Academy of Pediatrics, will be the guest lecturer. The course is sponsored by the University of Colorado Medical Center, the Rocky Mountain Pediatric Society and the State Department of Public Health.

Rocky Mountain Radio Series.—A thirteen week dramatization of medical subjects of particular interest to the Rocky Mountain region, sponsored by the Colorado State Medical Society and titled "Man and Medicine", will be offered to Colorado radio stations early in May. The first program of this local series, called "Beware of the Tick," is being offered stations in Alamosa, Boulder, Canon City, Colorado Springs, Denver, Durango, Fort Collins, Grand Junction, Greeley, La Junta, Lamar, Montrose, Pueblo and Trinidad.

CONNECTICUT

Annual Meeting of State Medical Society.—The Connecticut State Medical Society will hold its annual meeting at the Roger Ludlowe High School, Fairfield, April 28-29 under the presidency of Dr. James R. Miller. Papers will be presented by guest speakers each morning and symposiums and section meetings will be held each afternoon. The speakers include:

W. Edward Chamberlain, Philadelphia, Harmful Effects of Irradiation.
George C. Andrews, New York, What the General Practitioner Should Know about Dermatology.
E. Jefferson Browder, New York, Diagnosis and Treatment of Cranial Injuries.
Edward B. Tuohy, Washington, D. C., Integration of Anesthesiology in Medicine.
Emil Novak, Baltimore; Jacob Hoffman, Philadelphia, and J. Ernest Ayre, Montreal, Canada, Symposium on Gynecology.
Joseph Stokes Jr., Philadelphia, Infectious Hepatitis.
Charles R. Drew, Washington, D. C., Dehydration and Electrolytes.

There will be a symposium on alcoholism Thursday afternoon. The annual meeting of the Woman's Auxiliary will be on April 28 at the Brooklawn Country Club, Bridgeport, beginning at 1 p.m.

FLORIDA

State Association Meeting.—The annual meeting of the Florida Medical Association was held at the Ponce de Leon Hotel, St. Augustine, April 11-14 under the presidency of Dr. William C. Thomas, Gainesville. Among papers presented at three scientific sessions was "The Treatment of Anemia" by Dr. Russell L. Hader Cleveland, guest speaker. Twelve specialty societies met during the weekend preceding the association meeting. The Woman's Auxiliary also met April 12-13.

GEORGIA

State Medical Society Annual Meeting.—The annual session of the Medical Association of Georgia will be held in Atlanta April 27-30 under the presidency of Dr. Steve P. Kenyon, Dawson. The scientific program, beginning April 28, includes:

Henry K. Beecher, Boston, The Abner Wellborn Calhoun Lecture, Relief of Suffering Within the Hospital.
George H. Herrmann, Galveston, Texas, Coronary Artery Heart Disease.
Robert B. Lawson, Winston-Salem, N.C., Recent Concepts Regarding the Spread and Treatment of Poliomyelitis.
Thomas P. Findley Jr., New Orleans, New Concept Concerning the Pathogenesis of Certain Disorders Associated with Aging.

The President's Address on current problems of organized medicine will be given Thursday. Scientific and technical exhibits will be set up in the Academy of Medicine Building. The Auxiliary to the Association will meet in conjunction with the Academy of Medicine.

IOWA

Dr. Soley Appointed Dean.—Dr. Mayo Soley, professor of medicine and assistant dean at the University of California Medical School, San Francisco, has been appointed dean of the University of Iowa College of Medicine, Iowa City, effective July 1.

Dr. Soley will succeed Dean Ewen M. MacEwen, who died September 3, 1947. Dr. Soley will also serve as director of medical services of the University Hospitals and as a research professor in the Department of Internal Medicine. He is a graduate of Harvard Medical School, Boston, 1933, and has been associated with the University of California since 1935.

MARYLAND

Audiometric Testing Resumed.—The Baltimore League for the Hard of Hearing, Inc., has resumed its services for audiometric testing and the fitting of hearing aids, which will be done by appointment only. The League also conducts classes in lip reading and voice improvement for the hard of hearing. Moderate fees are charged those able to pay.

State Society Annual Meeting.—The Medical and Chirurgical Faculty of the State of Maryland will hold its annual meeting April 16-29 at the Sheraton Belvedere Hotel, Baltimore, under the presidency of Charles W. Maxson, Baltimore. Out of state speakers include:

Lee E. Sutton Jr., Richmond, Va., Early Diagnosis and General Pediatric Care of Poliomyelitis.
Col. Raymond O. Dart, Washington, D. C., Role of the Army Institute of Pathology in American Medicine.
John H. Gibbon Jr., Philadelphia, Diagnosis and Surgical Treatment of the Carcinoma of the Lung.
Winthrop M. Phelps, Children's Rehabilitation Institute, Cerebral Palsy Problem..
George F. Cahill, New York, Tumors of the Adrenal.
William S. Tillett, New York, Present Status of Pneumonia and its Clinical Problems.

MICHIGAN

Rural Medical Student Loan Fund.—A revolving loan fund to be known as the "Fund for the Encouragement of Medical Practice in Rural Areas" has been created by the Michigan Foundation for Medical and Health Education. A hundred man State Campaign Committee was recently formed with a goal of "$50,000 in Five Months," for the rural practice project. Announcement was made at a foundation breakfast March 11 at Detroit.

Children's Clinic Meeting.—The Detroit Pediatric Society and the Children's Hospital of Michigan Annual Clinic will hold a meeting in Detroit May 12-13. The program begins with a clinical conference at 5 p.m. at the Herman Kiefer Hospital. Following dinner at the Fort Shelby Hotel, Dr. Mitchell I. Rubin, Buffalo, will speak on "Kidney Infections in the Infant." On May 13 the following program will be presented at the Rackham Memorial Building.

William A. Evans Jr., Detroit, Obstruction of Alimentary Tract in Infancy.
Wolfgang W. Zuelzer, Detroit, Management of Purpura.
Warren E. Wheeler, Columbus, Ohio, Avoidance of Tracheotomy in Respirator Patients.
Paul V. Woolley Jr., Detroit, Management of Diarrhea.
James L. Wilson, Ann Arbor, Anaerobic Metabolism in Premature and Newborn Infants.

NEBRASKA

Annual State Medical Meeting.—The Nebraska State Medical Association will hold its eightieth annual assembly May 3-6 at the Cornhusker Hotel, Lincoln, under the presidency of Dr. George E. Charlton, Norfolk. Guest speakers from the University of Illinois College of Medicine, Chicago, will participate in a panel discussion on gallbladder disease following their presentation of papers Tuesday morning. They are:

Roger A. Harvey, Roentgenologic Diagnosis of Gastric Lesions.
Edmund F. Foley, Medical Aspects of Gastric Lesions.
John T. Reynolds, Surgical Treatment of Gastric Lesions.

On Wednesday members of the faculty of Duke University School of Medicine, Durham, N.C., will speak:

Edwin S. Orgain, Treatment of Cardiovascular Disease.
Guy L. Odom, Neurosurgery in Intractable Pain.
Elbert L. Persons, Medical Aspects of the Problem of Joint Disease.
Lenox D. Baker, Marie-Strümpel Arthritis and Undiagnosed Low Back Pain.

Panel discussions for the afternoon will be on lesions of the colon by members of the faculty of the University of Illinois and another on upper extremity pain by members of the faculty of Duke University. On Thursday morning papers will be presented by the following speakers from the University of Wisconsin Medical School, Madison:

Ralph E. Campbell, Management and Treatment of Prolonged Labor.
John E. Gonce, Meningitis in Infancy and Childhood.
Sture A.M. Johnson, Diagnosis and Treatment of Common Skin Diseases.
Edgar S. Gordon, Management of Thyroid Disease with Radioactive Iodine.

They will also participate in a panel discussion on diabetes. Other guest speakers will be Dr. Edward L. Compere, Chicago, "Poliomyelitis"; Dr. Paul Hawley, Chicago, "Prepayment Plans for Health Care;" and Charles S. Cameron, New York, "Cancer." The annual banquet will be Wednesday evening.

NEW YORK

Dr. Van DeMark Retires.—Dr. John L. Van DeMark, Rochester, director of Rochester State Hospital, retired from the New York State Department of Mental Hygiene January 16 and will be replaced by Dr. Kenneth K. Slaght, who entered the state hospital service in 1927 at Rochester. On his retirement Dr. Van DeMark was feted by his associates, employees of the hospital and friends.

"20,000 Years of Service."—The Medical Society of the State of New York has issued under the title "20,000 Years of Service" a commemorative booklet in honor of physicians who have served their communities fifty years or more. It is a beautiful booklet with a record of the ceremony in which Drs. Nathan B. Van Etten and Louis H. Bauer participated, and it includes also photographs and brief biographies of physicians who have practiced in New York more than fifty years.

Medical Care Plans Membership Grows.—The six New York State nonprofit voluntary medical care insurance plans approved by the Medical Society of the State of New York increased their membership 425,573, or 71 per cent, during 1947. Dr. Carlton E. Wertz, Buffalo, chairman of the Committee on Economics of the medical society, reported March 14 that over-all enrolment is 1,023,615. Benefits incurred for medical services to members in 1947 amounted to $3,681,555, representing over 110,000 claims.

New York City

Home Care of Cancer to Continue.—An experimental program beginning a year ago (THE JOURNAL, Feb. 1, 1947, p. 335) for treating patients with advanced cancer at home has been so successful that the New York City Cancer Committee has decided to allot $50,000 to the project. The program has been carried on by Montefiore Hospital. In the first year 1,540 medical calls were made. Social service workers and other specialists from the hospital staff and members of the Visiting Nurse Service of New York called on patients regularly.

Measles Epidemic.--According to newspaper reports, the incidence of measles is still rising in the city with 1,464 new cases reported for the week March 21-27. Since January 1 the health department has distributed free to physicians 21,423 doses of gamma globulin, which is more than three times the amount distributed in a corresponding time in 1946. So far this year, 9,215 cases and 7 deaths have been reported.

The Cleveland Cancer Award.—Dr. Cornelius P. Rhoads, director, Memorial Hospital for the treatment of Cancer and Allied Diseases, received the Clement Cleveland Award of the New York City Cancer Committee April 4 for work in cancer control during 1947. The award was made at a dinner that opened the 1948 fund drive for the American Cancer Society, Inc. The hospital is one of the principal beneficiaries of the local committee.

Open Institute for Cancer Research.—The Sloan-Kettering Institute for Cancer Research at Memorial Hospital Center for Cancer and Allied Diseases will open April 16. Sir Henry H. Dale, F.R.S., will speak at 9:30 a.m. Representatives of universities, technology and government and layman will make up the panel to discuss medical research. At a dinner in the Waldorf-Astoria, 7:30 p.m., the speakers will be Sir Henry H. Dale, Charles F. Kettering, Sc. D., Dayton, Ohio, and Dr. C. P. Rhoads, New York. The cornerstone of the institute, the central unit of the $15,000,000 Memorial Cancer Center, was laid April 7, 1947 (THE JOURNAL, May 3, 1947, p. 90).

Report on Tuberculosis.—Dr. Harry S. Mustard reported March 9 that the city's 18,000 cases of tuberculosis included 7,700 new cases, of which 17 per cent were in the minimal stage and 48 per cent in the advanced stage. In an address at the joint conference of the New York Tuberculosis and Health Association and the Tuberculosis Sanitorium Conference of Greater New York, he said that $309,000 was needed for purchase of new equipment and facilities for detection of tuberculosis. There was reduction of 5 per cent in the death rate from tuberculosis in New York in 1947. Health department figures show that for the first time deaths from tuberculosis fell below 40 per hundred thousand population. The death rate in the boroughs ranged from 27.8 in Queens to 73.1 in Manhattan. The rate for the city was 39.6.

NORTH CAROLINA

Annual Meeting of State Society.—The annual meeting of the Medical Society of the State of North Carolina will be held May 3-5 at the Carolina Hotel, Pinehurst, under the presidency of Dr. James F. Robertson, Wilmington. Guest speakers at the general sessions include:

R. E. Lapp, Ph.D., Washington, D. C., Atomic Warfare and Medicine.
John deJ. Pemberton, Rochester, Minn., subject to be announced.
Russel L. Haden, Cleveland, Treatment of Anemia.
William F. Friedewald, Atlanta, Ga., Pathogenesis, Diagnosis and Treatment of the Acute Phase of Poliomyelitis.

Section meetings will be on surgery, practice of medicine, gynecology and obstetrics, public health and education, neurology and psychiatry, pediatrics, radiology, practice of medicine and surgery, and ophthalmology and otolaryngology. President's Night on Tuesday includes a banquet at 7 o'clock to be followed by the President's Ball. Various societies and alumni associations will hold luncheons.

OHIO

Scientific and Technical Periodicals.—A list of scientific and technical periodicals in the libraries of greater Cincinnati will be published in May. It will show the holdings of fifty-eight public and industrial libraries and will contain 3,200 titles and more than 10,000 separate entries. This guide to the periodical resources of this area, particularly in chemistry, medicine and engineering, is being brought out under the sponsorship of the Cincinnati Section of the American Chemical Society for $2.50 postpaid.

Dr. Starin to Retire.—William A. Starin, Ph.D., of the Ohio State University department of bacteriology will retire from active service at the end of this academic year after thirty-eight years of teaching at the university. Plans are being made by friends and former students for a dinner in Dr. Starin's honor on May 8 at the Neil House in Columbus, and all friends and former students are invited to attend. Reservations must be made by May 1. The William A. Starin Lectureship has been established through the Ohio State University Development Fund and will be administered by the department of bacteriology in consultation with the dean of the graduate school. Contributions for the fund should be made payable to the Ohio State University Development Fund and sent to Dr. Margaret D. Heise, department of bacteriology, Pharmacy and Bacteriology Building, Ohio State University, Columbus. Reservations should also be made with Dr. Heise.

TEXAS

Dr. Williams Named Secretary.—Dr. Harold M. Williams, Fort Worth, former assistant secretary-editor of the State Medical Association of Texas, on January 17 was named secretary by the board of trustees. The office of secretary-editor became vacant on the recent death of Dr. Holman Taylor.

Dedication at College of Medicine.—Baylor University College of Medicine will hold a scientific program at the opening of the Roy and Lillie Cullen Building April 22-24 in Houston. Among the speakers on April 22 will be Dr. Chauncy D. Leake, president, University of Texas Medical Branch, Galveston; Dr. Ernst W. Bertner; Dr. Alton Ochsner, Tulane University of Louisiana School of Medicine, New Orleans; Col. A.A. De Coursey, San Antonio; Dr. Albert H. Holland, medical advisor to the Oak Ridge (Tenn.) Project of the U. S. Atomic Energy Commission, and William Houston, Ph.D., president of Rice Institute, Houston. Dr. Morris Fishbein, Editor of THE JOURNAL, will speak at 8 p.m. on April 23. Friday's program will include the following speakers: Dr. Benjamin B. Wells, Houston, director of education and research of the M.D. Anderson Hospital for Cancer Research; Dr. Francis J. Braceland, Mayo Clinic, Rochester, Minn., and Dr. Edwin C. Hamblen, Duke University School of Medicine, Durham, N. C. Three of the speakers on Friday afternoon will be Dr. Rolla E. Dyer, director of the National Institute of Health and special lecturer of the George Washington University School of Medicine, Washington, D.C., who will discuss "Research in Medical Sciences;" Dr. Henry M. Winans, clinical professor of medicine, Southwestern Medical College, Dallas, "Epileptic Equivalents as Cause for Somatic Symptoms" and Dr. Benjamin M. Baker Jr., internist at Johns Hopkins University School of Medicine, Baltimore, who will close the scientific session Friday afternoon. The principal speaker at the formal dedication will be Kenneth C. Royall, Secretary of War, who will speak on "Medical Education and National Defense."

State Medical Association Meeting.—The annual meeting of the State Medical Association of Texas will be held in Houston April 26-29 with headquarters at the Rice Hotel. Innovations in the program are an active section on general practice and an evening meeting designed especially for the lay public. At the lay meeting the speakers will be:

Lowell S. Goin, Los Angeles, Medicine Men and Doctors.
Haven Emerson, New York, It's Health Roundup Time in Texas; presentation of Dallas Health Museum Award.

Out of state speakers at the general sessions include:

Leo G. Rigler, Minneapolis, Routine Roentgen Examination of Symptomless Persons.
Waltman Walters, Rochester, Minn., Cancer of the Stomach.
Andrew B. Rivers, Rochester, Minn., Perforating Peptic Ulcers.
George F. Lull, Chicago, Secretary and General Manager, American Medical Association, Medical Legislation.
Willard O. Thompson, Chicago, Enodcrine Problems During Adolescence.
Ralph Luikart, Omaha, Reducing Fetal and Maternal Morbidity and Mortality by Controlled Nutrition During Pregnancy.
Frank H. Lahey, Boston, Management of Lesions of the Thyroid.
William L. Benedict, Rochester, Minn., Prevention of Blindness.
Jean V. Cooke, St. Louis, Leukemia in Children.
John A. Kolmer, Philadelphia, Synergistic or Additive Activity of Chemotherapeutic Compounds.
Wingate M. Johnson, Winston-Salem, N.C., Pancreatitis.

Sectional programs will also be presented. The usual clinical luncheons, president's reception and ball, alumni and fraternity banquets, past-presidents' association luncheon and golf tournament have been arranged. Scientific motion picture and technical exhibits are provided as between meeting features. The Woman's Auxiliary will meet in conjunction with the association April 26-29 with headquarters at the Lamar Hotel. Seven other related organizations will hold annual meetings.

GENERAL

Gastroscopic Society Meeting.—The American Gastroscopic Society will hold its fourth annual meeting at the Hotel Claridge, Atlantic City, N.J., May 2 under the presidency of Dr. Herman J. Moersch, Rochester, Minn. Subjects of papers to be presented include gastric polyps, involvement of the stomach in malignant lymphoma and flexible tube esophagoscopy.

Phase Microscopy and its Photographic Application. The Chicago Chapter of the Biological Photographic Association will meet April 20 at 7:30 p.m. at the University of Illinois Hospitals, 1853 West Polk Street, Room 221. Dr. Oscar W. Richards, Ph. D., Buffalo research biologist, will lecture on phase microscopy and its photographic application, illustrated with motion pictures.

Fellowship Examinations.—The Board of Examiners of the American College of Chest Physicians announces that the next oral and written examinations for fellowship will be held at Chicago June 17, 1948. Candidates who would like to take the examinations for fellowship in the college should contact the Executive Secretary, American College of Chest Physicians, 500 North Dearborn Street, Chicago 10.

Society for Psychosomatic Research.—The American Society for Research in Psychosomatic Problems will meet May 1-2 at Chalfonte-Haddon Hall, Atlantic City, N.J., under the presidency of Dr. Franz G. Alexander, Chicago. Halfday discussions will be devoted to psychosomatic aspects of genitourinary and gynecologic problems, psychosomatic problems of methodology in psychosomatic research and psychosomatic problems in diabetes.

Medical Relations in Business and Industry.—Wayne University School of Occupational Health will present its fifth series of Conferences on Medical Relations in Business and Industry on Wednesdays beginning April 28 and ending June 19. Conferences will open at 4:30 p.m., recess for dinner and reconvene at 7:15 p.m. Application for enrolment together with a check for $50 for the eight symposium-conferences should be mailed to the Dean of Wayne University School of Occupational Health, 1547 Penobscot Building, Detroit 26. The single conference fee is $10.

International Conference On Rheumatism. An International Scientific Conference on chronic degenerative rheumatism will be held June 24-27 at Aix-les-Bains, France, under the presidency of Professor Leriche. The conference will include titular members, who must be doctors of medicine or medical students, although the bureau reserves the right to accept all persons actively interested in hydrology and rheumatology; geologists, directors of spas, manufacturers of pharmaceutic products and others who furnish references. Communications should, if possible, be concerned with chronic degenerative rheumatism. Others are accepted at the discretion of the bureau. All correspondence should be addressed to Dr. Francon, 55 rue des Mathurins, Paris (8), who will accept advance registrations.

Medical History Meeting.—The twenty-first annual meeting of the American Association of the History of medicine will be held in Philadelphia May 26-27. All sessions (with the exception of the dinner) will take place at the College of Physicians. On Wednesday morning's program is a symposium on "Physician in the 18th Century." The Garrison Lecture will be delivered at 3 o'clock in the afternoon, and at 8 p.m. papers on the place of history in medical education will be submitted and discussed. In Thursday afternoon's general session, papers on miscellaneous subjects volunteered by members will be given. The dinner will be at 7 o'clock. Reservations should be made directly with Mr. Michael T. McGarry, Penn-Sheraton Hotel, referring in the letter to the meeting of the association.

Annual Dermatologic Meeting.—The annual meeting of the American Dermatological Association, Inc., will be held at the Hotel Del Coronado on Coronado Beach adjacent to San Diego April 26-29 under the presidency of Dr. J. Gardner Hopkins, New York. At an informal discussion scheduled for Monday at 2 p.m. new therapeutic ideas and diagnostic methods and other new suggestions will be presented and discussed. Among the subjects of papers to be read are:fleas in california, granular cell myoblastoma, eosinophylic granulomas of the skin, disseminate lupus erythematosus and seabathers' eruption. The Tuesday evening speaker will be Dr. Stafford Warren, dean and professor of biophysics, Medical School, University of California in Los Angeles, who will present "A Discussion of the Effects of Atomic Radiation on Human Tissues and Comments on Atomic Research." A recreational program has been arranged for late afternoon of each day.

National Heart Committee Formed. — The National Heart Committee, with headquarters in New York City, was recently formed to support pending legislation before Congress for the establishment of a National Heart Institute under the U. S. Public Health Service. Theodore R. Gamble, Washington, D.C., former assistant to the Secretary of the Treasury in charge of bond sales, is chairman. Among the sponsors of the National Heart Com-are Drs. Charles A. R. Connor, New York, president; Arlie R. Barnes, Rochester, Minn.; T. Duckett Jones, Boston; Irving S. Wright, New York; David D. Rutstein, Albany, N.Y.; Paul D. White, Boston; Howard Rusk, New York; Harry Goldblatt, Cleveland, and Henry S. Simms, Ph.D., New York. According to the committee, less than $3,000,000 a year of public and private funds is being spent on research in diseases of the heart and circulation, while $3,000,000 a year of public funds is currently being spent on research and control of plant and animal diseases.

CANADA

Public Health Association Conference.—The Canadian Public Health Association will hold its thirty-sixth annual meeting in Vancouver, British Columbia, May 18-20. The meeting is being sponsored by the British Columbia Department of Health with the Washington State Public Health Association as co-host. Canadian and American public health workers and all medical and nursing personnel are invited to attend. Sectional meetings will deal with epidemiology, sanitation, industrial hygiene, public health nursing, public health education, public health administration, nutrition and venereal disease. Annual meetings of the Washington State Public Health Association, British Columbia Public Health Workers and the Canadian Institute of Sanitary Inspectors will be held the day preceding the conference.

Deaths

George Barclay Wallace ⊕ New York; born in Detroit in 1874; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1897; studied at the University of Vienna and the University of Strasbourg; for three years instructor in pharmacology at the University of Michigan; joined the faculty of New York University College of Medicine in 1902 as an instructor; four years later became professor and in 1942 chairman of the department of pharmacology, retiring on Aug.31,1946; for many years professor of pharmacology at the New York University College of Dentistry; member of the American Society of Clinical Investigation, and of many other scientific societies; past president of the American Society of Pharmacology and Experimental Therapeutics, the Harvey Society and the Society of Experimental Biology and Medicine; served during World War I; veteran of the Spanish-American War; chairman of the committee on pharmacology and drugs of the 1939 World's Fair; member of the Committee on Drug Addiction of the Bureau of Social Hygiene; served as attending physician at the Almshouse Hospital and the Workhouse Hospital; later assistant physician at Bellevue Hospital and on the consulting staffs of the Central Neurological and Harlem hospitals; in 1934 received the honorary master of arts degree from the University of Michigan and in 1941 the doctor of science degree from New York University; in 1925 elected president of the Medical Alumni Association of New York University; on the thirty-sixth anniversary of his active teaching service in New York University College of Medicine, friends, alumni and students presented a portrait of him to the college; served as managing editor of the *Journal of Pharmacology and Experimental Therapeutics;* died in Bellevue Hospital January 15, aged 73, of cerebral hemorrhage and arteriosclerosis.

Albert Horr Montgomery ⊕ Chicago; born in Chicago Sept. 8, 1882; Rush Medical College, Chicago, 1907; professor of surgery at the University of Illinois College of Medicine; formerly on the faculty of his alma mater; member of the founders group of the American Board of Surgery; member of the Institute of Medicine of Chicago, Chicago Surgical Society, American Surgical Association and the American Association for the Study of Trauma; served as president and secretary of the Western Surgical Association; an officer serving overseas during World War I; retired in 1946 as chief of the surgical department of Children's Memorial Hospital; served on the staffs of Cook County and Presbyterian hospitals; died January 31, aged 65, of coronary artery disease.

Charles D. Allison, Gardner, Ill.; Medical College of Indiana, Indianapolis, 1896; died January 21, aged 76, of cerebral hemorrhage.

George Atcheson, Denver; Denver College of Medicine, 1893; member of the American Medical Association; affiliated with St. Luke's Hospital; died January 7, aged 80, of heart disease.

Florence Widney Austin ⊕ Dallas, Texas; Southwestern University Medical College, Dallas, 1908; died January 8, aged 60, of cerebral thrombosis.

Karl Roland Bailet, Boston; College of Physicians and Surgeons, Boston, 1910; Tufts College Medical School, Boston, 1913; served during World Wars I and II; deputy health commissioner of Boston; died in the New England Baptist Hospital Dec. 21, 1947, aged 61, of carcinoma of the liver.

Crescent Frank Balmenti, Youngstown, Ohio; University of Virginia Department of Medicine, Charlottesville, 1947; *interned* at the University Hospitals in Cleveland; died recently, aged 25.

Charles W. Banks, Orangeville, Ohio; Cleveland Homeopathic Medical College, 1899; died Dec. 8, 1947, aged 75, of heart disease.

Herbert Octavius Black, Waco, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1913; affiliated with the Veterans Administration; died in Hillcrest Hospital Dec. 19, 1947, aged 59, of heart disease.

Grace Mott Boswell, Cincinnati; Miami Medical College, Cincinnati. 1909; served on the staff of the Christ Hospital; died recently, aged 77, of arteriosclerosis.

Charles Lesley Boyers ⊕ Parkersburg, W. Va.; Maryland Medical College, Baltimore, 1900; affiliated with the Camden-Clark Memorial Hospital and St. Joseph's Hospital, where he died January 2, aged 70, of coronary occlusion.

Ronney Hunter Bridges, Shreveport, La.; Louisiana State University School of Medicine, New Orleans, 1944; interned at the Milwaukee County Hospital in Durham, N. C.; served in the medical corps of the U. S. Naval Reserve during World War II; died July 25, 1947, aged 26.

Robert Brittain ⊕ Downsville, N.Y.; Albany (N.Y.) Medical College, 1890; past president of the Delaware County Medical Society; village health officer; served during World War I, affiliated with the Margaretville (N.Y.) Hospital; died January 3, aged 80, of cerebral embolism.

William Cullen Bryant, Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1894; specialist certified by the American Board of Urology, Inc.; member of the American Urological Association; served as a member of the state board of medical education and licensure; died Dec. 23, 1947, aged 76.

Luther Francis Bugg, Carnegie, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1902; died recently, aged 72.

J. S. Butler, Superior, Neb.; Western Reserve University Medical Department, Cleveland, 1883; died Dec. 11, 1947, aged 90.

William Francis Carmody, Worcester, Mass.; Harvard Medical School, Boston, 1909; died recently, aged 78, of arteriosclerotic heart disease.

Knowles K. Carr ⊕ Devers, Texas; Kansas City College of Medicine and Surgery, Kansas City, Mo., 1917; served during World War I; died in Dayton (Texas) Memorial Hospital Dec. 24, 1947, aged 67, of cardiac failure.

Everette Virgil Conley, Cleveland; University of Louisville (Ky.) Medical Department, 1916; found dead in a water-filled ditch near Louisa, Ky., January 3, aged 55.

Thomas Egner Cooper ⊕ Davis, Calif.; St. Louis University School of Medicine, 1914; died Dec. 26, 1947, age 57, of coronary disease.

Joseph Thomas Croteau, Chisholm, Maine; University of Montreal Faculty of Medicine, Montreal, Canada, 1907; member of the American Medical Association; died in a hospital at Lewiston Dec. 14, 1947, aged 67.

Michael Francis Dean, Indianapolis; Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1907; member of the American Medical Association; died recently, aged 66, of coronary occlusion and diabetes mellitus.

Chertsey Hopkins DeJarnette, Staunton, Va.; Woman's Medical College of Pennsylvania, Philadelphia, 1894; served on the staff of the Western State Hospital; died Dec. 7, 1947, aged 79, of angina pectoris.

James E. Drane ⊕ Phoenix, Ariz.; University Medical College of Kansas City, Mo., 1896; affiliated with St. Monica's Hospital and Health Center, Good Samaritan Hospital and St. Joseph's Hospital, where he died Dec. 24, 1947, aged 75, of cerebral hemorrhage.

Urban Jacob Durner, Milwaukee; Marquette University School of Medicine, Milwaukee; 1913; member of the American Medical Association; served during World War I; affiliated with St. Joseph's Hospital, where he died Dec. 3, 1947, aged 57, of coronary occlusion.

Clifford S. Goodman ⊕ Chicago; University of Louisville (Ky.) Medical Department, 1912; served during World Wars I and II; died January 12, aged 56, of suffocation and burns received in a fire in his apartment.

Hugo Anton Engelhardt ⊕ Houston, Texas; Bellevue Hospital Medical College, New York, 1897: during World War II active in selective service work; on the courtesy staffs of St. Joseph's Infirmary, Methodist and Memorial hospitals; died recently, aged 73, of peritonitis.

John Nelson English, Gillespie, Ill.; Missouri Medical College, St. Louis, 1893; member of the American Medical Association; chairman of the board of directors of the Peoples State Bank; died in St. Francis Hospital, Litchfield, January 4, aged 81, of pneumonia.

Warren Dexter Fales, Silver Spring, Md.; Columbian University Medical Department, Washington, D.C., 1895; died in the Washington Sanitarium and Hospital in Takoma Park, January 18, aged 79, of arteriosclerosis.

Herman Albert Fasbender, Hastings, Minn.; University of Minnesota Medical School, Minneapolis, 1920; served as mayor; died in the Northwestern Hospital, Minneapolis, January 7, aged 53.

Ernest James Franklin ⊕ Indianapolis; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, 1920; died Dec. 11, 1947, aged 54.

Herbert William Fudge ⊕ Elmira, N.Y.; Niagara University Medical Department, Buffalo, 1893; fellow of the American College of Surgeons; served on the staff of the Arnot-Ogden Memorial and St. Joseph's hospitals; died January 9, aged 78.

Ray Thomas Fuller ⊕ Kalamazoo, Mich.; Saginaw (Mich.) Valley Medical College, 1903; affiliated with the Borgess and Bronson Methodist hospitals; died January 7, aged 72, of chronic nephritis.

Daniel Ignatius Gallagher ⊕ Lakewood, Ohio; St. Louis University School of Medicine, 1924; affiliated with the Lakewood (Ohio) Hospital and St. John's Hospital in Cleveland; died January 8, aged 49, of coronary thrombosis.

Harriet M. Allen Heath, South Pasadena, Calif.; Chicago Homeopathic Medical College, 1884; died Dec. 2, 1947, aged 89.

William Daniel Heaton, New York; Rush Medical College, Chicago, 1913; served in the U. S. Public Health Service during and after World War I; medical director of the New York Life Insurance Company; died January 14, aged 58, of heart disease.

Thomas Clark Hill ⊕ Huntington, Utah; University of Colorado School of Medicine, Denver, 1908; an officer during World War I; served as city physician and health officer; died Dec. 30, 1947, aged 63, of heart disease.

Thomas Jefferson Iles, New York; Vanderbilt University School of Medicine, Nashville, Tenn.; 1898, died in St. Barnabas Hospital recently, aged 79.

Ludwig Koempel, Brooklyn; Long Island College Hospital, Brooklyn, 1899; member of the American Medical Association; affiliated with the Bethany Deaconess Hospital; died Dec. 31, 1947, aged 81, of coronary thrombosis.

Joseph Roscoe Latham, New Bern, N.C.; Jefferson Medical College of Philadelphia, 1917; served during War I; formerly affiliated with the U. S. Public Health Service; at one time county coroner and health officer; medical director of St. Luke's hospital, where he died Dec. 29, 1947, aged 52.

John Kroulik, Nelsonville, Texas; University of Texas School of Medicine, Galveston, 1897; during World War I head of the county medical examining board for Selective Service; for many years a school trustee; president and director of the Industry State Bank; died in a hospital in Bellville Nov. 7, 1947, aged 75, of cerebral hemorrhage.

Thomas Adam Lawson, Dallastown, Pa.; Jefferson Medical College of Philadelphia, 1906; member of the American Medical Association; past president of the York County Medical Society; for many years director of the public schools in Dallastown; died Dec. 3, 1947, aged 68, of heart disease.

Lewis H. Long, Maysville, Ky.; Hospital College of Medicine, Louisville, 1894; member of the American Medical Association; president of the Mason County Medical Society; died January 9, aged 75.

Sergeant Price Martin, Kenmore, N.Y.; University of Pennsylvania School of Medicine, Philadelphia, 1921; member of the American Medical Association; at one time fellow in surgery at the Mayo Clinic in Rochester, Minn.; died January 8, aged 61.

Kirk Patrick Mason ⊕ Major, U. S. Army, retired; St. Petersburg, Fla.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1907; served during World War I; entered the medical corps of the regular army in 1920 as a captain; retired Sept. 30, 1934 for disability in line of duty; died July 28, 1947, aged 68, of cerebral hemorrhage.

John Bernhard Meneke ⊕ Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1904; affiliated with the Lankenau Hospital; died January 18, aged 64, of cerebral thrombosis.

Marshall William Meyer ⊕ Madison, Wis.; Rush Medical College, Chicago, 1927; health commissioner of Madison since Nov 1, 1947; formerly district health officer with the state board of health, serving at Ashland and at Green Bay as venereal disease control officer for the state board of health; fellow of the American Public Health Association; received his M.P.H. degree from the University of Michigan in Ann Arbor; died January 22, aged 46, of heart disease.

Robert Otto Meyer, Minneapolis; Kaiser-Wilhelms-Universität Medizinische Fakultät, Strassburg, Germany, 1888; served as clinical associate professor in the department of obstetrics and gynecology at the University of Minnesota Medical School; died Dec. 12, 1947, aged 83.

Virgil Orin Muench ⊕ Nichols, Iowa; State University of Iowa College of Medicine, Iowa City, 1910; served during World War I; affiliated with Mercy Hospital in Iowa City, serving as chairman of the staff; vice president of the local bank; died January 3, aged 62, of heart disease.

Willis Grafton Neally, Montclair, N.J.; Dartmouth Medical School, Hanover, N.H., 1907; an organizer and first president of the Greater New York Hospital Association; member of the American Hospital Association, medical director of the Brooklyn Hospital from 1912 to 1946, when he became medical director emeritus; died in the Mountainside Hospital January 7, aged 65, of coronary occlusion.

Francis Power Parker, ⊕ Charlottesville, Va.; Emory University School of Medicine, Atlanta, 1931; served during World War II; member of the Medical Association of Georgia; on the faculty of the University of Virginia Department of Medicine; formerly on the faculty of his alma mater; died recently, aged 41, of heart disease

Frank Benjamin Parker, Roanoke, Va.; Hahnemann Medical College and Hospital of Philadelphia, 1904; died in the Lewis-Gale Hospital Dec. 14, 1947, aged 65, of carcinoma of the rectum

Horace Norton Parker ⊕ Trenton, N.J., University of Pennsylvania Department of Medicine, Philadelphia, 1907; urologist for the city bureau of health, died January 4, aged 64, of coronary occlusion

John Wilson Parker, Columbus, Ohio; Chicago Homeopathic Medical College, 1899; formerly health officer of London ;died Dec. 28, 1947, aged 71.

Harold Darby Parks ⊕ Lieutenant Colonel, M.C., U. S. Army, Lancaster, Texas; Jefferson Medical College of Philadelphia, 1931; interned at the Army Station Hospital, Fort Sam Houston; served during World War II; killed in an airplane crash in the jungles of Peru October 10, 1947, aged 39.

William Henry Probert, Berkeley, Calif.; Washington University School of Medicine, St. Louis, 1921; member of the American Medical Association; at one time associate professor of pathology at the New York Homeopathic Medical College and Flower Hospital in New York; served during World War II; died January 12, aged 54, of coronary occlusion.

Samuel Brown Pulliam ⊕ Paducah, Ky.; Chicago Homeopathic Medical College, 1902; for many years city commissioner, served during World War I; affiliated with the Riverside Hospital; died January 8, aged 78, of heart disease

William Henry Remer, La Crosse, Wis.; Chicago Homeopathic Medical School, 1904; member of the American Medical Association; past president of the Vernon County Medical Society; served during World War I; affiliated with St. Francis and La Crosse hospitals; for many years president of the Chaseburg State Bank in Chaseburg; died Dec. 21, 1947, aged 70, of rheumatic heart disease.

Philip Lee Ring, Bellaire, Ohio; Cleveland Homeopathic Medical College, 1905; died January 2, aged 75, of Parkinson's disease.

John Turner Rose, Vineland, N. J.; Baltimore Medical College, 1894; died in the Ivy Hall Sanitarium, Bridgeton, Dec. 17, 1947, aged 78, of cerebral hemorrhage and arteriosclerosis.

Eugene Paul Schaefer ⊕ Irvington, N. J.; Columbia University College of Physicians and Surgeons, New York, 1905; affiliated with the Irvington General Hospital, where he died Dec. 5, 1947, aged 66, of coronary occlusion.

Robert Felix Schanz ⊕ Rochester, N. Y.; University of Michigan Medical School, Ann Arbor, 1915; specialist certified by the American Board of Urology; member of the American Urological Association; served during World War I; affiliated with St. Mary's Hospital; died Dec. 30, 1947, aged 56, of Hodgkin's disease.

Benjamin Schnee, South Sioux City, Neb.; University of St. Andrews Conjoint Medical School, St. Andrews and Dundee, Scotland, 1935; city health officer; received the Bronze Star and Purple Heart decorations for service during World War II; affiliated with St. Vincent's Hospital and the Lutheran Hospital in Sioux City, Iowa; died Dec. 24, 1947, aged 37, of coronary thrombosis.

Otto W. Shelksohn, Dorrance, Kan.; Baltimore University School of Medicine, 1894; died in the Ellsworth (Kan.) Hospital Dec. 28, 1947, aged 77, of cerebral hemorrhage.

Mahlon Cross Smalley, Gladstone, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1897; died Dec. 11, 1947, aged 80, of cerebral hemorrhage and arteriosclerosis.

Jeff D. Smith, Violet Hill, Ark.; Memphis (Tenn.) Hospital Medical College, 1895; died in the Craig Hospital, Batesville, Dec. 31, 1947, aged 80, of bronchopneumonia

R. E. Lee Steiner, Salem, Ore.; Willamette University Medical Department, Salem, 1898; member of the American Medical Association; in 1937 resigned as superintendent of the Oregon State Hospital after thirty years of service; died Dec. 20, 1947, aged 78.

Edgar Blaine Stonesifer ⊕ Williamsburg, Ky.; Lincoln Memorial University Medical Department, Knoxville, Tenn., 1914; served on the county health department; local surgeon for the Louisville and Nashville Railroad; died in the Norton Memorial Infirmary, Louisville, Dec. 27, 1947, aged 62, of heart disease.

Daniel Joseph Sullivan ⊕ Manchester, N.H.; Tufts College Medical School, Boston, 1916; fellow of the American College of Surgeons; died Dec. 16, 1947, aged 56.

Bruce Stevens Weaver ⊕ Stamford, Conn.; University of Michigan Medical School, Ann Arbor, 1910; specialist certified by the American Board of Pathology, Inc.; member of the American Society of Clinical Pathologists; served on the staffs of St. Joseph's Hospital and the Stamford Hospital, where he died January 8, aged 65.

Gilbert B. Wimberley, Reform, Ala.; Medical College of Alabama, Mobile, 1892; member of the American Medical Association; past president of the Pickens County Medical Society; county commissioner of revenue; died in Tuscaloosa Dec. 13, 1947, aged 78, of cerebral hemorrhage.

George Irvin Yearick ⊕ Pittsburgh; Medico-Chirurgical College of Philadelphia, 1903; member of the American Psychiatric Association; served during World War I; resident physician at the Municipal Hospital, where he died Dec. 29, 1947, aged 77, of cerebral arteriosclerosis.

Therapeutic Social Clubs for Mental Patients

In order to promote the formation of therapeutic clubs for patients both in and out of mental hospitals a meeting was organized in London by the Institute of Social Psychiatry. Dr. J. Bierer, director of the institute, said that the experience of social clubs now extended over nine years. In their establishment many problems had to be faced: how to provide freedom of action and self government, including the mixing of the sexes, with existing regulations, traditions and responsibilities. If patients were put in charge, there was the risk that an aggressive patient might take possession of the club and misuse it for the exploitation of his aggressive instincts. On the other hand, if a psychiatrist or nurse were in complete charge, the patients would feel that they had no say in the matter. The best solution was to let the patients have charge of the club, members of the nursing and other staff to attend by invitation, but to have honorary members, including the medical superintendent, the matron and the psychiatrist. In a club of which he had experience a few marriages had taken place and proved suprisingly successful. Two friendships had to be interfered with in order that they might not develop into a more serious alliance; one concerned an epileptic person and the other a patient with multiple sclerosis. But in the majority of cases there was no reason to suppose that any harm would follow, either from the eugenic or human point of view. Conditions in the club approximated more or less to everyday life. The majority of the patients behaved more naturally in the club, which made it possible to use it for diagnostic purposes. A second club was established for chronic and deteriorated patients, and gave them some opportunity to exercise initiative.

Patients got so accustomed to active social life in the hospital that they missed it after discharge. This led to the formation of extramural clubs. This idea underwent a large extension when confronted with the great number of a social, solitary and retiring persons attending outpatient departments. In forming such clubs it was important to avoid any stigma; therefore the club premises were away from hospitals and the name of the club did not indicate its nature. In most of the clubs friends and relatives were also members. Some of these were potential patients, and thus the club was of assistance in prophylaxis.

Dr. Donald Blair, deputy superindendent of a mental hospital, thought that the maximum number of patients in a club should be between 40 and 50. It is important to have a nucleus of patients of reasonably high intelligence, and the regular attendance of a psychiatrist at club functions is important. These should include lectures, discussions, dances and dramatic performances.

New Hearing Aid to be Supplied Free Under National Health Service

True to its socialistic policy, the government is having manufactured a new hearing aid which will be supplied free to all persons with defective hearing. Most of the existing hearing aids use valves of American design and manufacture, and there has been difficulty in obtaining replacements. The government has now placed an order with the Mullard Wireless Service Company for 400,000 valves, and a similar number of "medresco" units are to be produced, together with 100,000 annual replacements, involving a total cost of $20,000,000 a year for the whole scheme. It is claimed that a remarkable advance in the British technic of manufacturing valves has enabled this country to enter a world market previously dominated by American manufacturers. The "medresco" unit is a wedge-shaped instrument with a maximum width at the top of 2 1/2 inches (6.35 cm.), reduced at the bottom to 1 1/2 inches (3.8 cm.). The over-all length is 3 1/4 inches (8.26 cm.), and it is 1 inch (2.54 cm.) thick. The unit houses an amplifier using two valves which are less than 1/2 inch (1.27 cm.) in diameter. On the other hand, the manufacturers of commercial hearing aids have, through their association, issued a manifesto claiming that the government hearing aid already is obsolete, as they have produced better types of hearing aids.

Venereal Disease in the Army

When the Norwegian army sent a contingent in 1947 to Germany, the prospect of extensive infection of the young Norwegians with venereal disease renewed an old problem. Were the military authorities to put preventives at the free disposal of all who intended to expose themselves to infection? To do so would raise the outcry that the authorities were condoning and actually conniving at immorality. But a *laisser faire* policy offered no attractive alternative, and in the end preventives won the day. Whereupon there was a storm of protest in the press at home, and the clergy and other influential members of the community invited every one to join in a protest against the new order. Counter protests followed, and at least one important women's organization joined in them. The Norwegian Storting, or Parliament, is to be bombarded by protests signed by thousands of signatories who look at the problem exclusively from the ethical aspect and who hope that the army authorities will be instructed to dissociate themselves from any patronage of preventives.

Dr. K. Grette, of the Norwegian Army Medical Service, reports that in the seven month period February to August 1947, 54 cases of syphilis, 154 of gonnorrhea and 9 of ulcus mollecutis were observed in the Norwegian contingent in Germany. The incidence of syphilis in this contingent was 13.5 per thousand, whereas it was only 2.1 per thousand in the army at home. The same remarkable difference was observed with regard to gonorrhea, for which the figures were 38.3 and 9.8 per thousand respectively. In about 25 per cent of the cases of venereal disease the names and addresses of the persons who infected the soldiers were reported, whereas at home some 60 per cent of the sources of infection were reported. Of 113 soldiers answering questions about the use of preventives, 99 said they had not used condoms, whereas 14 had done so. The rate of infection was much higher among the Norwegian soldiers enjoying a holiday in Holland, Belgium or Denmark than among those on duty in Germany.

Correspondence

AN INTERNATIONAL SCHOOL OF MEDICINE

To the Editor:—I note with interest the letter from Dr. Merl G. Colvin in The Journal, February 21, in which he proposes the establishment of an International School of Medicine. The problem of our responsibility and opportunity in meeting the needs of the foreign countries interest me greatly. The role of medicine and the health sciences is an extremely important one in the concept of present world affairs. The war has left us with a responsibility and an opportunity formerly expected of Europe, and, as Dr. Colvin's letter implies, this small world's health vitally affects our own health and economy. Too often in the past, however, foreign students whose countries present a different economic and social picture from ours have been sent to our schools, which of necessity educate and train men for situations as they exist in this country. Many have returned to their own countries, where they are often discontented or frustrated in the attempt to apply American plan. Others have failed to return to their countries.

The present needs of our own country and the enormous number of native applicants for the study of medicine finds most medical schools in a helpless position; nor are the schools adequately equipped in budget and facilities to encourage any increased registration, native or foreign. In the postdoctorate (residency) program we have a professional (not a medical school) training for specialization in this country. Like the undergraduate curriculum, this too has far too many applicants from our own country. There would be no great benefit to foreign countries if such opportunity were given their students. The problem of visas, subsidy and transcripts is a headache to any school which attempts or encourages opportunity for foreign students at any level. The time may come when individual schools may elect one area of foreign need and become better acquainted with those needs by visits of faculty members on leave. Nevertheless, it is apparent to me that this is no adequate solution to the whole problem.

It would appear to me that a separate school, not bound by too strict an interpretation of prerequisites but allowing variations and flexibility, would be worth considering. It is conceivable that some foreign students would be better served by a program somewhat similar to that of the Central Medical School of Fiji. Primarily for the native needs in the South Pacific Islands, outstanding young men of the various tribes are selected by this school for a two year course in which their native taboos, beliefs and customs are not forgotten. Phenomenal good to the tribe results in the return of these young men to take up the methods adapted to their environment. Hygiene, sanitation, recognition and treatment of certain diseases and minor surgery are remarkably handled. I fear the imposition of a strictly American medical education would be inappropriate and disastrous. There should be recognition of grades of needs and intensities of training, varying with the native background. To fit them for the practice of medicine in these United States would seem by comparison a costly waste and, at present, an impossibility.

FRANCIS SCOTT SMYTH, M.D.,
California.

FACTORS AFFECTING NEED FOR PHYSICIANS

To the Editor:—The editorial in THE JOURNAL February 28, p. 6267, " Is There a Shortage of Physicians? " *answers the " wolf cry " of the* government well. The editorial did not consider a few important factors. Most important, after estimating the birth rates and death rates for the future as well as the number of graduates in medicine, will be the extra time necessary with each patient in using new methods to do a fine grade of work as well as in heading off malpractice suits. And as new discoveries are made, how many more new specialities there will be.

A good example of the latter is allergy. The specialists are needed, but it is just that many more physicians removed from the field of general practice. American physicians are doing good work. Now, as the thoroughness of the work improves in such matters as better history taking, more thorough examinations and more laboratory aids, the more time it takes for each patient. That may be the reason for the apparent shortage of physicians. That is one reason why the ratio of physicians per thousand population must increase, but not at the expense of poor training.

People are better informed and demand better medicine. The economic level in this country is high. Many cases of hernia, varicose veins, blemishes and a few hundred other pathologic conditions are receiving attention that would be neglected if finances were at a low level.

J. W. ROBINSON, M.D.,
Los Angeles.

ASPHYXIA OF THE NEWBORN

To the Editor:—May I comment on the query on page 358 of THE JOURNAL, January 31, " Asphyxia of the Newborn?" Predelivery oxygen administered to the mother is probably only effective if administered for fifteen to thirty minutes prior to delivery and discontinued as the presenting part passes the perineum. Observation indicates that uterine contraction which diminishes the area of placentation decidedly reduces the interchange of blood gasses. Such change in the size of placentation naturally results when there is decrease in the contents of the uterine cavity. I agree that respiratory movements precede delivery.

Unpublished studies in 1931 and 1932 indicated that the oxygen content of fetal cord venous blood at the instant of delivery average from 1.5 to 2.4 mg., per hundred cubic centimeters, and in a occasional case the oxygen content was even lower. The carbon dioxide content was 15 to 18 mg. Therefore predelivery oxygen to the mother is necessary so that the cells of the respiratory center will be oxygenated enough to be able to respond to the stimulus of increased carbon dioxide tension. Such increased carbon dioxide tension will work properly on a newly oxygenated cell and continue the respiratory movements initiated during intrauterine life.

I agree that heavy analgesia and anesthesia depress intrauterine respiratory activity and, if still present in the postdelivery circulation, depress extrauterine respiratory activity. Therefore, all of the preceding premise is based on the use of analgesia and anesthesia which is controlled to an optimum point of success without damage.

LOWELL F. BUSHNELL, M.D.,
Los Angeles.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and the Examining Boards in Specialties were published in THE JOURNAL, March 27, page 896.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: Examination. Montgomery, June 22-24, 1948. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery 4.

ARIZONA:* Examination. Phoenix, April 6-7. Endorsement. Phoenix, April 19. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

ARKANSAS:* Examination. Little Rock, June 3-4. Sec., Medical Board of the Arkansas Medical Society, Dr. L. J. Kosminsky, Texarkana. Eclectic: Little Rock, June 3. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

CALIFORNIA: Oral. San Francisco, June 5-6; Los Angeles, Aug. 7-8. Written Examination. San Francisco, June 7-10. Los Angeles, Aug. 9-12. Oral and Clinical Examination for Foreign Graduates. San Francisco, June 6. Sec., Dr. Frederick N. Scatena, 1020 N Street, Sacramento 14.

COLORADO:* Examination. Denver, June 21-23. Final date for filing application is June 5. Endorsement. Sec., Dr. J. B. Davis, 831 Republic Bldg., Denver.

DELAWARE: Examination. Dover, July 13. Endorsement. Dover, July 22. Sec., Dr. J. S. McDaniel, 229 S. State St., Dover.

FLORIDA:* Examination. Jacksonville, June 29-30. Sec., Dr. Harold D. Van Schaick, 6675 Windsor Lane, La Gorce Island, Miami Beach 41.

HAWAII: Examination. Honolulu, July 12-15. Sec., Dr. S. Doolittle, 881. S. Hotel St., Honolulu.

IDAHO: Boise, July 13-15. Sec., Bureau of Occupational Licenses, Miss Estella S. Mulliner, 355 State House, Boise.

ILLINOIS: Chicago, April 6-8. Supt., Dept. of Registration and Education, Mr. Fred W. Ruegg, Springfield.

INDIANA: Examination. Indianapolis, June 1948. Sec., Board of Medical Registration and Examination, Dr. Paul R. Tindall, K of P Bldg., Indianapolis.

KANSAS: Kansas City, June 9-10. Sec., Board of Medical Registration & Examination, Dr. J. F. Hassig, 905 N. 7th St., Kansas City.

KENTUCKY: Examination. Louisville, June 16-18. Sec., Dr. P. E. Blackerby, 620 S. 3d St., Louisville.

MARYLAND: Medical Examination. Baltimore, June 15-18. Sec.-Treas., Dr. Lewis P. Gundry, 1215 Cathedral St. Baltimore. Homeopathic Examination. Baltimore, June 15-16. Sec., Dr. J.A. Evans 612 W. 49th St. Baltimore.

MINNESOTA:* Minneapolis, April 20-22. Sec., Dr. J. F. DuBois, 230 Lowry Medical Arts Bldg., St. Paul.

MISSISSIPPI: Jackson, June 1948. Asst. Sec., State Board of Health, Dr. R. N. Whitefield, Jackson.

MISSOURI: Examination. St. Louis, May 24-26. Final date for filing application is April 24. Exec. Sec., Mr. John A. Hailey, State Capitol Bldg., Jefferson City.

MONTANA: Helena, April 5-7. Sec., Dr. O. G. Klein, First Nat'l Bank Bldg., Helena.

NEBRASKA:* Examination. Omaha, April 5-7. Dir., Mr. Oscar F Humble, Room 1009 State Capitol Bldg., Lincoln 9.

NEVADA: Carson City, May 3. Sec., Dr. G. H. Ross, 215 N. Carson St., Carson City.

NEW JERSEY: Examination, Trenton, June 15-17. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

NORTH CAROLINA: Endorsement. Pinehurst, May 4. Sec., Dr. Ivan Procter, 226 Hillsboro St., Raleigh.

NORTH DAKOTA: Grand Forks, July 6-9. Sec., Dr. G. M. Williamson, 4½ S. 3rd St., Grand Forks.

NEW YORK: Examination. Various Centers, June 28 - July 1. Sec., Dr. J. L. Lochner, Education Bldg., Albany.

OHIO: Endorsement. Columbus, April 6. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus 15.

OKLAHOMA:* Oklahoma City, June 2-3. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

OREGON:* Endorsement. Portland, May 7-8. Final date for filing application is April 23. Sec., Miss L. M. Conlee, 608 Failing Bldg., Portland.

PENNSYLVANIA: Examination. Philadelphia & Pittsburgh, July. Act. Sec., Bureau of Professional Licensing, Mrs. M. G. Steiner, 351 Educational Bldg., Harrisburg.

SOUTH CAROLINA: Written Examination. Columbia, June 21-23. Endorsement. April 5. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

SOUTH DAKOTA:* Pierre, July 20-21. Sec., Dr. Gilbert Cottam Capitol Bldg., Pierre.

UTAH: Examination. Salt Lake City, June, 1948. Asst. Dir., Department of Registration, Miss Rena B. Loomis, 324 State Capitol Bldg., Salt Lake City.

VIRGINIA: Examination. Richmond, June 18-19. Endorsement. Richmond. June 17. Sec., Dr. K. D. Graves. 306 Medical Arts Bldg., Roanoke.

WEST VIRGINIA: Charleston, April 5-7. Comm., Public Health Council, Dr. N. H. Dyer, State Capitol Bldg., Charleston.

WISCONSIN: Examination. Madison, April 3. Sec., Dr. W. H. Barber, Scott & Watson Sts., Ripon.

Medical Motion Pictures

FILM REVIEWS

Observations on Hepatitis. 16 mm., black and white, sound, 1,200 feet (one reel), showing time thirty minutes. Prepared in 1946 by Joseph Stokes Jr., M.D., professor of pediatrics, University of Pennsylvania, Philadelphia. Produced by and procurable on loan from Mead Johnson & Company, Evansville, Ind.

This is a lecture film in which numerous charts are used in illustration. The film concerns largely an epidemic of infectious hepatitis in a Jewish children's camp near Philadelphia. Careful studies were conducted on the epidemiology of the illness. The causative agent was isolated and studied. This film is suitable for showing to physicians interested primarily in public health, pediatricians, internists and medical students.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Revocation of License for Gross Immorality in Connection with Diabetes Treatment.—In a proceeding before the state board of medical registration and examination the respondent's license to practice medicine was revoked, but on appeal to the circuit court the revocation was set aside. The board therefore appealed to the Supreme Court of Indiana. The petition seeking revocation of the respondent's license was based solely on the ground that respondent was guilty of "gross immorality" in the practice of medicine and, said the Supreme Court, the only question before the circuit court was therefore whether or not the decision of the board was based on "a substantial factual foundation."

The respondent was admitted to practice medicine, surgery and obstetrics in the state of Indiana in 1897 and for one year prior to October 6, 1946, he maintained his office, designated at times as a diabetic institute, in South Whitley, Ind. During this period this office had at least 100 patients a day, and there were over sixty rooming houses in South Whitley taking care of these patients. In October 1945 the respondent and his brother practiced at that office. They made representations to patients that they could cure diabetes and on at least one occasion made such representations to an admitted diabetic person who had been suffering from the disease for at least six years. They also told her that she could eat about anything and gave her a diet sheet which stated that most anything that has been made with sugar that has been thoroughly cooked is beneficial to one suffering from this disease. A pamphlet distributed at the institute, and prepared by the respondent's brother, who was associated with him, disclosed that they were doing business under the name of "Kaadt Diabetic Institute." This pamphlet contained a foreword wherein it was stated that there was real hope for the diabetic person through their method of treatment; that the principal method of treatment employed was an internal medicine taken by mouth; that in a majority of cases the patient resumes a normal diet within two or three weeks after beginning the treatment, and that in a large number of cases recovery had occurred. Patients were advised to attend the institute for three days, for which there was a charge of $30.00 including board; on leaving they were given a three months' medical treatment to take home with them, for which there was a charge of $30.00. The medicine which was to be taken home consisted of 1 gallon of liquid in a glass container, the liquid consisting of vinegar to which had been added potassium nitrate, some pepsin and takadiastase. The wholesale cost of this liquid medicine was 93 cents per gallon. In addition the patient was given a box of cathartic and digestive pills to take during his home treatment.

The board's evidence showed that the respondent prescribed for patients without any physical examination and that he prescribed and gave medicine for diabetes to persons who were free from that disease. In no case was the necessary blood test made for sugar before prescribing for patients. Insulin and diet are the only known and accepted methods of treatment for diabetes; there is no oral treatment recognized by the medical world; removing patients suffering from this disease from insulin is dangerous and may be fatal. The consumption of sugar by a diabetic person is injurious to him, and the fact that sugar has been cooked does not render it harmless. The treatment adopted by the respondent is not approved by any other person in the profession. There have been no clinical tests or experimental stage in the development of this medicine; the treatment and medicine prescribed by the respondent is of no benefit to diabetic persons. The giving of the same has at times injured the patients, and some have died from its effect.

In order for the foregoing evidence to establish gross immorality, said the Supreme Court, we must conclude that it is sufficient to support the inference that the practice complained of was not an honest effort to relieve suffering but was a scheme for unjust enrichment. The important question is what the respondent knew to be the facts. If the treatment was not a cure or a proper remedy for diabetes, and he knew this to be a fact, then he was guilty of a scheme to defraud. It has been said, the Supreme Court continued: "That false and fraudulent representations may be made with respect to the curative effect of substances is obvious. It is said that the owner has the right to give his views regarding the effect of his drugs. But state of mind is itself a fact, and may be a material fact, and false and fraudulent representations may be made about it; and persons who make or deal in substances or compositions alleged to be curative are in a position to have superior knowledge, and may be held to good faith in their statements. It cannot be said, for example, that one who should put inert matter or a worthless composition in the channels of trade, labeled or described in an accompanying circular as a cure for disease, when he knows it is not, is beyond the reach of the lawmaking power."

The respondent contended that to empower the board to pass on his good faith would have a crippling effect on advances in medicine science, as it would prevent the use of new remedies. With this we cannot agree, said the Supreme Court. A physician is not limited to the most generally used of several approved modes of treatment, and the use of another mode known and approved by the profession is proper, but every new method of treatment should pass through an experimental stage in its development, and a physician is not permitted to make untested experiments on patients.

In conclusion the Supreme Court noted that the respondent was a man of broad professional experience, sufficiently educated in his profession. The board was therefore justified in not attributing the acts complained of to mistake arising out of inexperience or lack of knowledge. Accordingly, the Supreme Court was of the opinion that there was sufficient competent evidence in the record to support the finding of the board, and the board's order revoking the respondent's license was therefore sustained.—*Board of Medical Registration and Examination of Indiana v. Kaadt, 76 N. E. (2nd) 669 (Ind., 1948).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

Gastric Secretion with a Mucin Antacid Mixture.—A new antacid consisting of a mixture of mucin, aluminum hydroxide and magnesium trisilicate has been compared by Kammerling and Steigmann with other currently used antacids concerning its effect on gastric acidity. The mixture appeared to decrease acidity in a higher percentage of cases, and this antacid effect seemed to last longer than with other substances. There seemed to be less rebound of the acidity with this substance. It is palatable, easily taken and has a better antacid effect when chewed carefully before swallowing it.

Surgery in Ulcerative Colitis.—Best believes that the treatment for ulcerative colitis is primarily medical, and that about 90 per cent of the cases will respond to it to a greater or lesser degree. He reviews the dietetic management, the measures directed toward minimizing intestinal spasm, the use of sulfonamide drugs, blood transfusions and psychsomatic factors. Appendicostomy and cecostomy are to be condemned. Colostomy of the transverse colon is justified in the infrequent segmental ulcerative colitis involving the left side of the colon. Ileosigmoidostomy is seldom justified, as it is most unusual to find ulcerative colitis involving only the proximal colon and leaving the rectum and sigmoid free from invasion. In only one of the author's cases did ileosigmoidostomy seem indicated, and to date, at the two year period, the result appears quite satisfactory. The author has seen 2 patients, who were subjected to primary ileosigmoidostomy by other surgeons when the rectum was apparently free of the disease, in whom there developed a severe ulcerative proctitis within a few months. Ileostomy is the procedure usually indicated. The type and position of the ileostomy stoma are important. The loop ileostomy should be used only in extreme emergencies. The end type ileostomy is preferable. In a recent check of 71 consecutive cases of ulcerative colitis only 9 patients were subjected to surgical intervention. Eight of these were given ileostomies. Two emergency ileostomies were performed, of which 1 was fatal. The 6 patients with elective ileostomies recovered. The ninth patient to undergo operation recovered following an ileosigmoidostomy. Among the 63 patients not operated on there were 2 deaths. There is not sufficient evidence that early ileostomy in ulcerative colitis will result in permanent cure of the disease. The author is of the opinion that it is far better to have a few patients arrive too late for surgery than to subject too many to unnecessary surgery, which to be of value is rather mutilating and usually leaves the patient with a permanent ileostomy.

Metastatic Calcification of Sclera Following Use of Vitamin D.—Frost and his associates report the case of an elderly woman who five years prior to admission first noticed arthritic pains in her hands, shoulders, elbows and knees. Her physician placed her on treatment with a proprietary brand of vitamin D. She continued to take this preparation for a period of three and one-half years, taking an average dose of two and a half capsules daily (125,000 units). Studies on the calcium metabolism of this patient revealed that although vitamin D therapy had been discontinued eight months previously, hypercalcemia persisted and on a low intake of calcium a relatively high excretion of calcium was maintained in the urine. In addition there was evidence of diminution of renal function. Calcium deposits into the sclera and cornea were prominent features. These studies support the view that administration of large doses of vitamin D may have a prolonged effect lasting over a period of months.

Tularemia Treated with Streptomycin.—Johnson and his associates report on streptomycin therapy of 5 patients with tularemia. In each case the handling of wild rabbits was the source of infection. Two patients with the typhoidal type of the disease and 1 of the 3 with the ulceroglandular type were critically ill on admission. Systemic manifestations of the disease were promptly controlled, and the primary ulcer healed in less than half the usual time. Lymphadenopathy subsided promptly in a patient treated early but progressed to suppuration in another treated late. Neither intramuscular nor intraglandular injection of streptomycin in a patient with a suppurating node could obviate the need for adequate surgical drainage. Streptomycin therapy does not alter the immunity response, since agglutination titers tend to rise as in untreated cases.

Role of Liver in Renal Sulfonamide Complications.—Kuzma and Polley say that the role which liver plays in renal sulfonamide complications is emphasized by the frequency of such developments in chronic hepatic diseases and in instances of hepatic injury due to sulfonamide compounds. In a previous report 14 cases of renal sulfonamide complications were described and the hepatorenal relationship was considered. Since that time 5 additional fatal sulfonamide complications have been studied, making a total of 19. The incidence of hepatic disease as a background in renal sulfonamide complications is emphasized by the presence of hepatic damage in 6 cases of fatal nonobstructive sulfonamide nephrosis. Lesser hepatic lesions were found in 4 additional patients, 3 of them with sulfonamide lithiasis, making a total of 10 cases. The specific nature of the hepatic lesion is not as important as the fact of diffuse liver impairment and is not correlated with the seriousness of renal injury. Liver diseases of nutritional deficiencies anemia. Administration of iron is the most important part of the treatment of this type of anemia; 15 to 45 grains (0.97 to 2.91 Gm.) of ferrous sulfate are given daily in divided doses with or after meals. Liver therapy is not indicated and is a needless expense. Folic acid is ineffective. The macrocytic anemias, particularly pernicious anemia are characterized by large cells which are well filled with hemoglobin, have a color index over 1 and high cell indexes. Folic acid is as effective in producing and maintaining blood regeneration at satisfactory levels in macrocytic anemias as is liver extract. It does not, however, protect against degenerative changes in the central and peripheral nervous system which frequently develop in persons with addisonian pernicious anemia; nor does it reverse these neurologic changes once they have developed. Folic acid is indicated in macrocytic anemia accompanying or secondary to pregnancy, pellagra, hepatic disease or gastrointestinal disorders. Sprue and in particular nutritional and pernicious anemia require diagnostic differentiation, as folic acid alone is not sufficient in the latter.

Acute Bronchiolitis in Children. J. H. Benward.—p. 24.

Lipomas of Intestine.—Tenner reports 12 cases of lipomas of the large and small intestines, which produced symptoms and which were removed surgically. Lipomas occur more commonly in the large intestines. The average age at which they presented themselves by producing symptoms was 53 years in this series. Pain was the major symptom. Vomiting associated with pain was present in over half of the cases. Diarrhea and constipation was variable. There was weight loss in the majority of cases. Ulceration of the mucosa covering the lipomas was present in all but 1 case. This can be due to pressure injury as in intussusception or to trauma as in partial obstruction, or to infarction as from pressure on the blood vessels from the growth and development of the tumor. In spite of the incidence of ulceration blood was infrequently found in the stool. In many cases the preoperative diagnosis is that of a malignant neoplasm. This frequent error is due to the obstructive nature, the age of the patient and the loss of weight. Treatment is surgical. Local excision of the growth and direct closure or anastomosis is the ideal procedure when the lesion is not too extensive. Another procedure is a resection of the segment of bowel which contains the tumor.

Metabolism of Cinchonine in Dogs and In Man. J. C. Andrews and W. E. Cornatzer.—p. 246.

Transportation of Exotic Anophelines by Airplane.—The possibilities of aeronautic transportation of mosquito vectors of disease has been appreciated, according to Miller and his co-workers, for about twenty years. International quarantine regulations of 1933 and 1944 include measures to combat this danger. Analysis of the records of inspections at Miami, Brownsville and New Orleans during the past three years indicates that about 6 per cent of inspected planes harbored mosquitoes. If those recovered are regarded as representing 10 per cent of the mosquitoes actually present, conformable published data of one year provide transportation-rate indexes per one hundred planes of about 1 exotic mosquito and 0.3 to 0.6 exotic anophelines; if 11 per cent of these were alive, these rates indicate a hypothetic maximum of 10 to 20 viable exotic specimens of Anopheles in thirty thousand planes. The chances for a yearly importation of this magnitude to result in implantation of new anopheline species in the United States seem slight, in view of the many factors that can be expected to militate against their effective establishment. Despite the theoretically small chance of significant importation of exotic species, prudence and past experience require that quarantine precautions be maintained by mosquito control around airports; disinsectization of planes with improved methods and routine surveillance of exposed areas to detect incipient breeding of imported anophelines.

Hepatic Destruction of "Pentothal."—Shideman and his collaborators say that prior to 1940 it was assumed that "pentothal" was degraded primarily in the liver, but studies carried out after that seemed to indicate that the liver is not of outstanding importance in the inactivation of this drug. This lack of harmony induced the authors to use various in vivo and in vitro technics to determine whether or not the liver degrades "pentothal" and two other thiobarbiturates. In mice they found that hepatic damage due to carbon tetrachloride significantly prolonged the duration of effect of "pentothal sodium" and two other thiobarbiturates. Subtotal hepatectomy in rats produced a significant prolongation of the duration of action of "pentothal." Diminished blood flow through the liver, as produced by the Eck fistula technic in rats, increased the duration of action of "pentothal" and the two other thiobarbiturates tested. "Pentothal" was degraded in vitro by slices and minced portions of rat liver.

Mistaken Diagnoses of Tuberculsois. R. H. Kaplan and L. Levin.—p. 29.

Bismuth Therapy of Verrucae.—O'Connor and Tweedall employed oral administration of *sodium bismuth triglycollamate* ("bistrimate tablets") in the treatment of 14 patients with verrucae. The drug was administered after meals. Each tablet contained 410 mg. of sodium bismuth triglycollamate equivalent to 75 mg. of metallic bismuth. The dose varied from a minimum of three tablets to nine tablets daily. The case histories indicate that medication was continued for three weeks or longer. Eight of the 14 patients were completely cured, in that the multiple verrucae disappeared without trace; 4 patients showed improvement, and 2 did not manifest improvement. In 2 cases it was necessary to withdraw the drug because of intolerance. However, in 1 of these the verrucae disappeared entirely two weeks after cessation of therapy and in the other there was definite improvement at the time the drug was stopped.

Book Notices

Headache. By Louis G. Moench, M.D., Assistant Clinical Professor of Medicine, University of Utah School of Medicine, Salt Lake City. Cloth. Price, $3.50. Pp. 207, with 58 illustrations. The Year Book Publishers Inc., 304 S. Dearborn St., Chicago 4, 1947.

This small book is well organized and the subject matter is discussed in an orderly manner. There are ten chapters, all of which are rather short but comprehensive. The author draws freely on the experience of others and at the end of each chapter includes a well-selected bibliography. It would appear that a single bibliography at the end of the book would have avoided needless repetition of references. In chapter 1 the pathologic anatomy and physiology of headaches is discussed in simple terms. The mechanism of headache is made to appear rather simple. This may be true at times, but frequently in clinical work the mechanism of a given headache is difficult to demonstrate. In the succeeding chapters the author considers headaches from intracranial pathology, cranial nerve neuralgias, headache of ocular origin, headache of nasal origin and so forth. The final chapter deals with headache of emotional origin. This important chapter is well written, but in keeping with the size of the book it is all too short. In the discussion of headaches occurring after spinal puncture, the author calls attention to the fact that patients who are permitted to be up and about after the spinal puncture are less likely to have headaches than those confined to bed for twenty-four hours. In the discussion of meningitis several reports of cases are reviewed, which add little to the discussion of the subject of headaches or to the treatment of meningitis. Post-traumatic headache is given but limited space. The suggestion that neostigmine is helpful in treatment of post-traumatic headaches is not always borne out by clinical experience. Cervical arthritis as a cause of early morning headache may be somewhat overemphasized. No special mention is made of temporal arteritis as a cause of headache. The author has condensed in some two hundred pages a satisfactory review of the subject of headaches, and one may well recommend the book to medical students and physicians.

Contribuição para o estudo hematológico e clínico da anemia perniciosa (moléstia de Addison-Biermer). Por Michel Abu Jamra. Tese apresentàda à Faculdade de medicina da Universidade de São Paulo para o concurso de docência-livre, São Paulo. Paper. Pp. 316, with 31 illustrations. Emprêsa gráfica da "Revista dos Tribunais," Ltda., São Paulo, 1947.

The greatest value of this monograph on pernicious anemia lies in the completeness with which the author has reviewed the present knowledge of the subject. The bibliography is remarkably complete and will be of value to all workers in the field. The monograph opens with a detailed consideration of the pathogenetic mechanisms of anemia and a suggested new classification which seems to offer no advantages over the etiologic classification already in use for many years. Important stress, however, is laid on the constitutional and nutritive aspects of the etiology of pernicious anemia. The author has suggested subdivisions of the disease according to the predominance of anemic, gastrointestinal or neurologic symptoms and signs This emphasis seems unwarranted except to draw attention to the occasional case of combined system disease with little or no anemia. Studies of the urine of normal and pernicious anemia patients for antianemic activity were negative. The evidences for the maturing effect of the antipernicious anemia principle on megaloblastic marrow are reviewed. The theory that the excess bilirubin and urobilinogen comes from material incompletely synthesized into hemoglobin rather than from hemolysis and hemoglobin breakdown is supported. Studies on changes in plasma proteins and blood volume before and after therapy are reported and discussed. Alterations in the gastrointestinal secretions and bacterial flora and the sequelae of these changes are described in detail. The revival and extension of some of the pre-liver treatment theories is timely in view of certain evidences that such changes may play a role in producing megaloblastic anemia, e. g., the pernicious anemia-like picture occurring in association with multiple intestinal stenoses, the experimental production in animals on deficient diet that are given indole of an anemia which responds to liver extract. The extensive way in which the field of knowledge of pernicious anemia and related states is covered makes this monograph a most useful reference book on the subject. Unfortunately, owing to the rapid expansion of knowledge of folic acid, most of the more recent developments have taken place since the monograph was published. However, as the literature on the subject is confusing and had not led to satisfactory explanations of the mode of action of folic acid and its relationship to liver extract, this lack is not serious and does not detract from the merits of the book.

Electrocardiografía clínica con estudio de derivaciones unipolares. Por el Dr. Sergio Alvarez Mena, Instructor de la Facultad de medicina, Habana. Fabrikoid. Price, $10. Pp. 568, with 210 illustrations. M. V. Fresneda (Editor), Neptuno 561, La Habana, Cuba, 1947.

The author bases his textbook primarily on the concepts of F. N. Wilson and D. Sodi Pallares, to whom the book is dedicated. A short outline is given of cardiac anatomy and physiology, and the fundamentals of electrophysiology are discussed. "Unipolar" leads and the electrical axis are dealt with in great detail, the ventricular gradient is taken up in a special chapter, and the second half of the book is devoted to the arrhythmias and to clinical electrocardiography. Unfortunately, in some illustrations the tracings are mounted upside down; in other figures, shown for the demonstration of arrhythmias, much longer strips should be presented. Definite misinterpretations can be found, like that of a premature systole of sinus origin in figure 92 and of paroxysmal ventricular tachycardia in figure 139, the latter obviously an artefact; flutter with supposedly 3:1 auriculoventricular conduction is shown in figure 107; figure 96 is described as normal sinus rhythm, yet it shows an auricular tachycardia with 2:1 block. It is not clear why the author classifies premature systoles with inverted P waves and shortened PR interval as auricular premature systoles and not as auriculoventricular nodal in origin. The book is modern in its approach, and the author is familiar with the recent contributions to electrocardiography by American authors. It is to be hoped that the next edition will show the necessary corrections and some additional illustrations to make this volume a valuable book for the student of electrocardiography.

La pathogénie des altérations électrocardiographiques de la péricardite: Etude clinique et expérimentale. Por Eduardo Coelho, professeur à la Faculté de médecine de Lisbonne, Lisbonne. Conférence proférée à l'Académie suisse des sciences médicales (Zurich). Paper. Pp. 74, with 58 illustrations. The Author, Lisbon, 1947.

This monograph is based on the experience of the author with 138 cases of acute and chronic pericarditis (constrictive and nonconstrictive) of various etiology. It excludes the pericarditis associated with stenocardia. It analyzes the electrocardiographic data before and after operation. In 6 cases histologic examination of the myocardium was made at necropsy. The author refers to but does not document his results with experimental pericarditis, local and generalized, in dogs and monkeys. On the basis of these observations the author concludes that the mechanism for the electrocardiographic alterations is due to bioelectrical changes in the epicardium. In the 6 cases examined by the author he found no evidence of histologic changes in the subepicardial myocardium. He reports that in animals injury within the myocardium does not cause changes in the electrocardiogram, whereas injury at the surface does. It is well known, as the author found, that myocardial damage not surfacing on the epicardium (or endocardium) causes no injury currents, but it is difficult to see how injury of the lining of the heart, the epicardium, can. It is generally agreed that injury of the myocardium which surfaces on the epicardium is the primary cause of the injury effect seen in the electrocardiogram in pericarditis. It is apparent that injury effects may be present in the subepicardium which cannot be demonstrated histologically. Therefore, the evidence presented does not exclude this possibility. The author presents an adequate review of the literature and is familiar with the work of others. It is regrettable, however, that he did not include a bibliography.

Physiology of Man in the Desert. By E. F. Adolph and associates. Monographs in the Physiological Sciences. Cloth. Price, $6.50. Pp. 357, with illustrations. Interscience Publishers, Inc., 215 Fourth Ave., New York 3, 1947.

This volume is a comprehensive report of the investigations done by the Rochester Desert Unit during the period from 1942 through 1945. Incidentally, it is also the first volume in the series entitled "Monographs in the Physiological Sciences" sponsored by an editorial board of distinguished physiologists. The studies were conducted in the Colorado desert in California and in the Desert Laboratory at the University of Rochester. In the course of the presentation the entire subject of heat regulation and water balance is outlined and discussed in a clear fashion. The material is well integrated in spite of the fact that the chapters were written by a number of different contributors. Sweat formation, dehydration and water requirements, thirst, circulation and blood changes during water deprivation are extensively considered. Many important practical conclusions are drawn; a complete list of specific instructions in regard to food, shelter, clothing and water are presented and their physiologic rationale is given. This book is remarkable for its correlation of practical and theoretic aspects of the subject; its contents should be of interest to the research scientist, the physician and the climatologist. These studies are a good example of the important basic physiologic knowledge that can come out of the solution of practical problems.

Der Myokardinfarkt: Erkennung, Behandlung und Verhütung. Von Professor Dr. Max Hochrein, Direktor der Medizinischen Universitätspoliklinik Leipzig, Leipzig. Band I, Kreislauf-Bucherei, herausgegeben in Verbindung mit der Deutschen Gesellschaft für Kreislaufforschung. Third edition. Paper. Pp. 387, with 82 illustrations. Theodor Steinkopff Verlagsbuchhandlung, Embaumstrasse 2, Frankfurt am Main-Griesheim, 1945.

This third edition summarizes the author's experiences and is based on over 700 personal cases of myocardial infarction. The reviewer has not seen the second edition, which appeared in 1941, but on comparing this edition with the first, it is apparent that the entire subject has been greatly expanded, this edition being double the size of the first. The book is taken up primarily with a consideration of the clinical aspects of this condition, the experimental background having been abbreviated as the author's own experimental experiences have dimmed and as his interest has become more and more clinical. This edition was written during the war with its inevitable handicaps. The literature is carried through to 1941, but the American and English publications which appeared during the war and which contributed greatly to the subject are not covered. This leads to obvious defects. The presentation of the electrocardiogram is inadequate and not commensurate with present standards in this country. It is hoped that when the fourth edition appears these defects will be remedied.

Deep Analysis: The Clinical Study of an Individual Case. By Charles Berg, M.D., D.P.M., Physician to the British Hospital for Functional Mental and Nervous Disorders, London. Cloth. Price, $3.50. Pp. 254. W. W. Norton & Co., Inc., 101 Fifth Ave., New York 3, 1947.

This book is a highly illuminating description of a complete psychoanalysis of a single case. The patient under analysis, who subsequently attained a position of national eminence in England, did not present himself with any especial symptoms but because of a deeply felt dissatisfaction with his own mode of life. However, Dr. Berg only too quickly during the course of the analysis was able to point out that under the cloak of normality this man concealed all the ingredients of every psychopathologic formation and mechanism including frigidity, impotence, hysteria, obsession and even paranoia and schizophrenia. The uncovering of these phenomena provided the author with an excellent opportunity to discuss lucidly these aberrations from a theoretic point of view. Many will disagree with the author on his method and some of the technics applied, but the analysis was handled in a masterly fashion. His theoretic discussion as well as the manner of the unfolding of the case will be instructive to every student of psychoanalysis. The nonpsychiatric physician will find the book fascinating.

Massage and Remedial Exercises in Medical and Surgical Conditions. By Noël M. Tidy. Seventh edition. Cloth. Price, $6. Pp. 480, with 190 illustrations. William Wood & Co., Mount Royal and Guilford Aves., Baltimore 2, 1947.

This book, written by a physical therapist for physical therapists in Great Britain, has had seven editions since 1932. Its well merited success is due to a broad and conservative presentation of the subject matter, which has grown to impressive proportions in successive editions. Each of the twenty-three chapters includes an adequate discussion of pathology, symptomatology and general medical treatment, followed by a full presentation of all forms of physical treatment. This is quite different from the run-of-the mill books on massage. Almost two hundred illustrations and a full index add to the usefulness of the volume, which has been serving as chief guide for the examinations of the Chartered Society of Masseurs and Medical Gymnasts. Physical therapists trained on the level of this book should become invaluable technical assistants indeed to the medical profession.

Endocrinologia sexual femenina. Par Carlos J. Calatroni, docente libre de clinica ginecológica, Buenos Aires, Vicente Ruiz, jefe del Serv. de ginecología del H. español, Buenos Aires, y Guillermo di Paola, docente libre de Clínica ginecológica, Buenos Aires. Prólogo del Profesor Dr. Bernardo A. Houssay. Cloth. Price, 68 pesos. Pp. 724, with illustrations. Libreria y Editorial "El Ateneo," Florida 340, Córdoba 2099, Buenos Aires, 1947.

This book is printed on enamel paper and many of the illustrations are reproduced in color. Luis Seoane's sixteen modernistic drawings are an unusual feature. Since endocrinology has revolutionized gynecology in the past twenty-five years, the aim of this book is to affirm fundamental principles of diagnosis and treatment. Dr. Houssay states in the prologue that the authors have had ample clinical and laboratory experience to enable them to give a clear, critical, up-to-date review of endocrine physiology, pathology and therapy in the female.

The authors believe that excessive brevity conspires against clarity of presentation. The book is divided into three sections. Part I is a description of the embryology, anatomy and physiology of the female in intrauterine life, childhood, adolescence, the period of sexual maturity and the menopause. The various somatic modifications are stressed. Three types of sexual cycles are outlined, namely, the diphasic, triphasic and monophasic. A chapter is devoted to anomalies of the diphasic cycle. This section of the book contains interesting clinical material and is well illustrated by photomicrographs, diagrams and photographs of patients. Treatment is given in detail, including tables of commercial drugs and their equivalents. Part II is concerned with the physiology of the hypophysis, the chorioplacental system, the suprarenals and the thyroid as they affect the female. Part III is devoted to the female sex hormones, i. e., gonadotropins, prolactin, estrogens and progesterone, with indications and contraindications for their use. There is an appendix of miscellaneous terse quotations and an index.

This book, because of its clarity of arrangement and illustrations, is easy to understand even though the potential reader may not be familiar with the Spanish language.

Fundamentals of Psychiatry. By Edward A. Strecker, M.D., Sc.D., LL.D., Professor of Psychiatry and Chairman of the Department, Undergraduate and Graduate Schools of Medicine, University of Pennsylvania, Philadelphia. Fourth edition. Cloth. Price, $4. Pp. 325, with 21 illustrations. J. B. Lippincott Co., 227-231 S. Sixth St., Philadelphia 5, 1947.

This is a small compendium describing, in easily understandable language, the basic fundamentals of psychiatry. The author emphasizes the relation between internal medicine and psychiatry, and for this reason this manual is good for students, general practitioners, nurses and psychiatric social service workers. This manual is a useful and accurate summary of psychiatry.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

SULFAMERAZINE

To the Editor:—I have reviewed the literature which has appeared in *The Journal* during the past four years on sulfamerazine. 1. Are the blood levels of sulfamerazine and sulfadiazine comparable, or does the fact that nearly twice as much sulfamerazine is bound to proteins mean that it is half as effective when comparing equal concentrations of the two drugs? 2. Does concentration of sulfamerazine in the spinal fluid equal 50 per cent or 80 per cent of the plasma concentration? 3. Should a urine alkalinizer be used with sulfamerazine? 4. What is the accepted dose in children? 5. What is the status of the drug as far as the other sulfonamide compounds are concerned?

M.D., Indiana.

Answer.—The whole blood levels of sulfamerazine and sulfadiazine are not strictly comparable for two reasons.

1. Sulfamerazine enters the red cells in low concentration (25 per cent), while sulfadiazine does so easily. Thus blood levels (determined by the usual whole blood method) indicating as much sulfamerazine as sulfadiazine represent plasma levels containing more of the former drug.

2. About twice as much sulfamerazine has been found under certain conditions to be bound to plasma proteins as sulfadiazine. However, the actual percentage of each drug bound is dependent on several factors: first, the most important being the actual concentration of the drug since the percentage bound decreases as the total concentration increases; second, the blood protein level itself is important in determining the degree of binding. As can be seen arithmetically, the actual percentage bound is important and this varies with the level being considered. Therefore, because of the several factors involved, it is difficult to state exactly the meaning of relative blood levels, except that it appears probable that higher whole blood concentrations of sulfamerazine than of sulfadiazine are needed to have equal therapeutic activity, since such activity has been shown to depend solely on the unbound drug.

The spinal fluid concentration of sulfamerazine in relation to its plasma concentration is again variable. However, in cases of meningitis the spinal fluid level is about 50 per cent of the whole blood level (somewhat under 50 per cent of the plasma level). In patients without meningeal inflammation the spinal fluid concentration is nearer 25 per cent of the whole blood concentration.

Attempt should be made to alkalinize the urine when using sulfamerazine. There is no one accepted dose in children, but the dose usually used is the same as for sulfadiazine—0.05 Gm. per pound per twenty-four hours.

Sulfamerazine is an alternate drug of choice to sulfadiazine. It is probably best used to try to avoid reactions when sulfadiazine has previously been administered. Because of poorer penetration into the spinal fluid, it may not be as effective in the treatment of meningitis. Sulfadiazine may be somewhat superior in infections with Klebsiella organisms and in bacillary dysentery.

GRAY HAIR IN CHILDREN

To the Editor:—What causes gray hair during adolescence? What are effective therapeutic agents in treatment?

T. D. Lee, M.D., Portland, Ore.

Answer.—Gray hair in young children and adolescents is uncommon. One patient developed iron gray hair at 5 years of age. He grew up, went through college, played football and engaged in other sports, but the iron gray hair persisted. Therapeutic agents of benefit are not known. The vitamin calcium pantothenate will change the color of hair in animals but it has no effect on man.

SMALLPOX VACCINATION

To the Editor:—Are there reports of congenital malformations or miscarriage attributable to smallpox vaccination during pregnancy? If the mother has not been previously immunized, is vaccination of the mother during the puerperium contraindicated?

Captain, M.C., U. S. Army.

Answer.—Congenital malformations or miscarriage apparently cannot be attributed justly to smallpox vaccination during pregnancy. There is no contraindication to vaccinating the mother during the puerperium, if she has been exposed to smallpox.

COLOMBIAN EPIDEMIC

To the Editor:—Please give me information on the diagnosis and treatment of an epidemic disease which prevails in a large territory of a rural zone of Colombia. This epidemic appeared in a group of villages which form one of the zones of coffee plantations about 50 kilometers from Cucuta city. The villages are about 1,500 meters above sea level. The villagers are frequently unclean and have body lice. Ticks abound. The houses are made of straw. The disease has attacked persons of every age and condition.

The first 4 cases were fatal within twenty-four hours. One case is followed by several in a family. The disease begins suddenly with chills followed by high fever, which remits slightly during the eight to fifteen days of its duration. Within six to twelve hours after the onset petechial spots appear on the feet, legs and arms, a few on the trunk and none on the face. The petechiae are dark in color with polycyclic borders and about 1 cm. in diameter. They may be abundant or scanty. There is a sensation of local burning. One of the patients presented the rash twice with an interval of four days.

Photophobia, conjunctival injection, typhus tongue, somnolence in some cases, moderate splenomegaly and serous effusion in the elbow and wrist joints, which spontaneously reabsorbs in a few days, also occur. Articular fluid is scanty, forearms are held in flexion and legs in extension. Moderate headache, vomiting, peribuccal herpes, congestion of the lungs and cough also occur. Arterial tension averages 110 mm. systolic and 60 to 70 mm. diastolic; the pulse rate is 120 a minute. Reflexes are exaggerated.

There are also polymorphonuclear leukocytosis, moderate eosinophilia, anemia, urobilinuria and negative Weil-Felix and Widal reactions. Subcutaneous inoculation with a sample of the liver, suspected of Rickettsia, in 2 guinea pigs produced no effect on the animals. Smears and cultures for Clostridium chauvoei and for hematozoic parasites gave negative results. Microscopic studies for Rickettsia were not carried out. The patients had 3 Gm. daily of para-aminobenzoic acid. Some patients had a moderate remission; in others the drug had no effect. The population has had vaccine for prevention of exanthematic typhus. Please suggest additional diagnostic methods.

Benjamin Rojas Pacheco, M.D., Cucuta, Colombia.

Answer.—The clinical symptoms of the patients and the epidemiologic information, plus the known existence of rickettsial diseases in Colombia, justify the suspicion of an epidemic of typhus in the Cucuta area.

However, the epidemiologic studies and clinical symptoms together with a negative Weil-Felix suggest meningococcemia caused by one of the four types or groups of meningococci, Neisseria intracellularis.

Extensive meningococcic epidemics with high fatality have been reported in some areas of South America. Fulminating cases with signs of collapse and shock from the onset are occasionally observed in meningococcic infections. The neurologic symptoms reported from Cucuta do not indicate extensive infection of the meninges, but deaths associated with severe adrenal hemorrhages have occurred within less than twenty-four hours in other places with little or no extension of infection to the meninges.

The disease most frequently attacks the young, but persons of any age or condition are susceptible. The onset is usually sudden with chills, high fever (often with remissions), headache, nausea, vomiting, meningeal irritation and frequently petechial cutaneous lesions which are variable in appearance and distribution. Peribuccal herpes are frequently observed. Ocular symptoms, including conjunctivitis, and involvement of the nose and throat, pharynx and lungs may occur. Lobar or bronchial pneumonia has been observed frequently as a complication in some outbreaks. The tongue may have the appearance seen in typhus. The spleen is usually enlarged in acute cases. Frequently there is constipation. Arthritis, some with serous or purulent exudation, has been reported to be the most frequent complication in some epidemics. Leukocytosis in most cases remains constant.

Positive microscopic and cultural examinations of the spinal fluid and blood will confirm the diagnosis. Cultures should be made of material from the nasopharynx of patients and suspected carriers.

Rickettsial complement fixation and agglutination reactions should be continued for confirmation or ruling out of the rickettsial diseases.

In order to investigate the possibility of other diseases, epidemiologic studies should be intensified, detailed recordings of clinical data should be continued and thorough blood examinations and other laboratory studies should be made.

INTOXICATION

To the Editor:—Will a person who takes concentrated alcoholic drinks become intoxicated sooner than one who takes diluted alcoholic drinks, assuming that the time interval and total alcoholic intake is the same?

M.D., Illinois

Answer.—When fairly large doses of alcohol are ingested, e. g., 55 cc. absolute alcohol, the maximum blood alcohol concentration occurs with a 30 per cent aqueous dilution of the ingested alcohol. Greater or lower concentrations of ingested alcohol cause lower maximum concentrations in the blood (Lolli.

G., and Rubin, M.: *Quart. J. Stud. on Alcohol* **4**:360, 1943). The intoxicating effect of alcohol increases with rising concentrations of the same amount of alcohol and then decreases with further concentration. The slower absorption of alcohol with higher concentrations is probably the result of damage to the gastric mucosa. Newman and Abramson (*ibid.* **3**:361, 1942) administered the same amount of alcohol as Scotch whisky and California port wine. The blood alcohol curve for the whisky showed a peak in one hour, but the peak from the wine was much lower and occurred in two hours. The intoxicating effect of the wine was correspondingly lower than that of the whisky. When sugar was added to the distilled liquor, there was no difference in the action of the whisky and the wine. The presence of food in the stomach and of buffers in the beverage are important factors in the intoxicating effects of alcohol.

PYODERMA OR "JUNGLE ROT"

To the Editor:—A man aged 30 contracted "jungle rot" of the hypothenar eminence of the palm. Treatment included antibiotics, salicylic acid, coal tar and mercurial antiseptics without relief. Finally it responded to a full dose of roentgen therapy two years ago. The same condition has now recurred in the same location and is spreading. What other therapeutic agents are suggested? Can the course of roentgen therapy be repeated?

M.D., New York.

Answer.—"Jungle rot" is not a clinical entity. It is a term used by the men in the armed services in the South Pacific for a number of cutaneous diseases, usually pyoderms. Most cases were irritant dermatitis or fungous disease which had become secondarily infected with pyogenic organisms. Ecthyma, diphtheritic lesions and traumatic ulcers were also part of the inclusive term, jungle rot.

The lesions on the palms might be ringworm, particularly the id type from a focus of dermatophytosis on the feet; psoriasis, either the dry or pustular type, or the entity known either as recalcitrant eruption or pustular bacterid. The latter is more likely to be strikingly symmetric on the thenar eminences and consists of pinhead-sized pustules in the epidermis which dry *in situ* to leave small brown scabs. Contact dermatitis, a fixed drug eruption or sensitization to a food might also account for the eruption.

Eczematoid ringworm is the disease most frequently encountered. Treatment depends a good deal on the character of the lesions. If they are vesicular, relief can be obtained from cool wet packs of aluminum subacetate in 0.5 per cent solution. If there are scaly patches, an ointment containing salicylic acid and benzoic acid in dilute form is usually effective. The ointment should be applied also to any focus of ringworm that is present in the toes, particularly in the interspaces. For eczematous patches, a preparation containing tar may be useful.

If topical measures fail to effect the desired improvement, it is likely that after an interval of two years more roentgen therapy would be useful. It is assumed, of course, that the skin shows no evidence of damage from roentgen rays.

VISUAL ACUITY

To the Editor:—A patient has vision of 10/100 in his right eye, which corrects to 20/40, and vision of 3/100 in his left eye, which corrects to 15/100. What is the percentage of loss of vision in his left eye?

He has a small scar over half of the pupil of his left eye, as a result of ulcer following injury by a foreign body: otherwise his eye seems perfectly normal. What test is recommended to determine malingering?

W. C. Behen, M.D., Lansing, Mich.

Answer.—Vision of 15/200 represents a loss of 63.4 per cent of visual efficiency for distance. Distant vision is, however, but one element in the determination of ocular efficiency. The amount of disability is computed by obtaining the product of efficiency value of central visual acuity (average of near and far), the field of vision and muscular function. A standard method for the appraisal of loss of visual efficiency was adopted by the Section on Ophthalmology in 1926 and modified in 1940 (*Tr. Sect. Ophth., A. M. A.,* 1941, pp. 329-337), but standards vary considerably from state to state.

No specific test may be recommended to expose simulated defective vision, and the examiner's patience and ingenuity may be extended to the utmost before the fraud is exposed. The tests depend in general on (1) varying the size of the visual angle subtended by the test letter and (2) determining the vision with both eyes of the patient open but with the patient using only the "poorer" eye, the vision of the opposite eye being suppressed by means of prisms, mirrors, polaroid disks, colored lenses and test letters, or instruments, several of which have been devised to uncover malingering. There is a good discussion of the tests and their application by M. A. Lasky (Simulated Blindness, *Arch. Ophth.* **25**: 1038, 1941).

VASECTOMY

To the Editor:—How long a period of time must elapse following vasectomy before the patient can be certain of being absolutely sterile? Should microscopic examination of the seminal fluid be done before assuring the patient that he is sterile?

Glenn T. Howard, M.D., Pearsall, Texas.

Answer.—Following vasectomy one month should elapse before a specimen of seminal fluid is examined for the presence of sperms. If sperms are found, the examination should be repeated in another thirty days. Obviously, the patient may not be assured of his sterility until the seminal fluid is free of sperms. Recanalization is unusual following a properly performed vasectomy, in which the cut ends of the vas are doubled back and tied. Interposition of the scrotal tissues is also desirable in preventing recanalization.

DR. RUSKIN'S THEORY AND TREATMENT

To the Editor:—One of my patients, whose disease has been diagnosed as ruptured intervertebral disk, has found his way to Dr. Simon L. Ruskin of New York. Dr. Ruskin has a novel form of treatment as outlined in an article, "The Control of Muscle Spasm and Arthritic Pain Through Sympathetic Block at the Nasal Ganglion and the use of the Adenylic Nucleotide; Contributions to Physiology of Muscle Metabolism," which appeared in the *American Journal of Digestive Diseases* (**13**: 311-320 Oct. 1946). There are numerous favorable case reports in the article Please inform me as to the efficacy of this form of therapy.

Sidney B. Meltz, Richmond Hill, N. Y.

Answer.—Ruskin's treatment is based on a rather complicated theory. He proposes that "the underlying biochemistry of contractile elements which would characterize all muscle spasm (of *both smooth and striated muscle) would tend to be the same.*" A "reflex neurogenic factor in muscle spasm" is also postulated. Ruskin sees a close relationship between such conditions as acute and chronic arthritic pain, hypertension, coronary artery spasm migraine, menstrual pains and ureterai colic, in all of which conditions his treatment presumably is indicated and is equally successful. Anesthetization of a sympathetic nerve center (the sphenopalatine ganglion) is said to be "followed by immediate generalized relaxation of muscle spasm, not only of smooth muscle such as the arterial tree but of striated skeletal and syncitial cardiac muscle."

According to Ruskin, he began these studies in 1924 and has treated patients "numbered in the thousands." Despite a quarter-century of such studies and the supposed "dramatic nature of the results," this and a companion paper appear to be his first reports on the treatment as applied to arthritis, and confirmatory work by others has not yet appeared. Fifty representative cases were reported in such meager detail that the reader cannot form independent opinion as to diagnosis. The clinical diagnoses were couched in such vague terms as "chronic arthritis," "rheumatic arthritis," "lumbosacral spasm (sacro-iliac)" and "muscle tonus disturbance." Roentgenographic reports were usually absent and roentgenographic illustrations or photographs of end results were not presented.

Success in treatment was claimed in about every case (except for 1 patient who later was found to have a protruded intervertebral disk), but the length of the follow-up time usually was much too short (sometimes as short as two weeks) for one to be able to express an opinion as to the final outcome.

The treatment combined three procedures: sympathetic block at the nasal ganglion, the intramuscular injection of ferrous adenylate into one buttock and calcium ascorbate into the other buttock. No control studies on the effect of any one of these procedures used alone were reported. The statement was simply made that "without spheno-palatine ganglion block neither the adenylate nor the calcium ascorbate relieved the spastic state."

ACTINOMYCOSIS

To the Editor:—In *The Journal,* Dec. 13, 1947 under Queries and Minor Notes, in answer to a question about the latest treatment for actinomycosis nothing is said of the use of thymol, which has apparently had good effect in the few cases where it has been given a fair trial. Please refer to "Thymol Therapy in Actinomycosis" by H. B. Myers, (*The Journal,* May 29, 1937, p. 1875) in which this pharmacologist details recoveries in 5 of 6 cases treated; also see "Pulmonary Actinomycosis. Recovery after Thymol Therapy" by Etter and Schumacher (*The Journal,* Sept. 9, 1939, p. 1023), in which perfect recovery ensued after adequate doses of thymol. As detailed in our report, extensive pulmonary lesions cleared completely as demonstrated by roentgen ray after the administration of 2 Gm. thymol by mouth daily for seventeen days. To my personal knowledge this man has remained well for eight years. He showed absolutely no response to massive doses of iodides and roentgen therapy. Because of the excellent results achieved by Myers and because of the spectacular recovery in our case it is my opinion that thymol should at least be mentioned as meriting a trial in such an otherwise almost hopeless condition.

CARDIOVASCULAR SYSTEM AS THE EFFECTOR ORGAN IN PSYCHOSOMATIC PHENOMENA

GEORGE BURCH, M.D.
and
THORPE RAY, M.D.
New Orleans

Bodily functions have been known for many years to be disturbed by emotional stress. These physiologic disturbances may be manifested as symptoms referable to any organ system; e. g., the gastrointestinal tract, the genitourinary tract and the respiratory and cardiovascular systems. For unknown reasons there is a tendency for one system to predominate in its disturbances. Many isolated observations of these reactions have been described. Beaumont[1] described interesting observations concerned with formation of gastric juice. Although most of Pavlov's studies were concerned with conditional reflexes, many were related to disturbed psychic states. Cannon[2] conducted objective studies of gastrointestinal disturbances produced by psychic changes. Wolff and Wolf and their associates[3] observed directly the effect of psychic disturbances on the vascularity of the mucosa of the stomach and changes in secretion in the stomach and duodenum associated with emotional upsets. The effect of emotional stress on respiration has been shown to produce a different spirographic respiratory pattern from that of the normal relaxed subject.[4] Sighing respiration is commonly observed during periods of emotional stress, and its importance in diagnosis has been previously emphasized.[5] Increased depth of respiration has been demonstrated during unpleasant thoughts.[6] Respiratory disturbances may be reflected in the cardiovascular system because of close physiologic relationships; e. g., the pronounced vasoconstriction following deep inspiration[7] or the influence of respiration on venous return. These indicate the complicated integrations of psychosomatic dysfunctions among organ systems.

The extreme susceptibility of the cardiovascular system to psychic disturbances is particularly well known. Every one is familiar with the development of tachycardia following emotional experiences, hypertension, pallor of the skin and syncope with fear angina pectoris with excitement and hypertension with prolonged anxiety. In fact, the cardiovascular system has been claimed to be "the most frequent seat of vegetative manifestation of neurosis."[8] Symptoms referable to the heart occur in almost all neuroses.[5b] The temporary cardiovascular reactions of blushing, sweating, paling, changes in temperature, and so forth, are better known than the more subtle and often sustained reactions to prolonged emotional stress. Studies on the cardiovascular output during periods of emotional stress reflect the effect of the central nervous system on the cardiovascular system. Anxiety causes a considerable increase in cardiac output.[9] The increase in cardiac output is out of proportion to the consumption of oxygen[10] and may be independent of changes in blood pressure. Studies of Hickam and Cargill[9b] revealed an increase in cardiac output in medical students before examinations of 50 per cent over the "composed" level. The greatest increase was 180 per cent. Anxious patients show an increase during the resting state. Recalling unpleasant life situations has been shown to produce changes in blood pressure, cardiac output and respiration which were as great as those produced by exercise. Anger, fear, resentment,

10. Wolf and Wolff.[5c] Stead, Warren, Merrill and Brannon.[9c]

frustration and depression produced a greater cardiac output, which remained elevated for a longer period of time than the usual response to a standard exercise test.[5c] Under emotional stress the efficiency of the cardiovascular system is definitely impaired; therefore sustained emotional stress is a burden on the cardiovascular system. Psychic trauma may act as the precipitating cause of heart failure.[11]

The occurrence of angina pectoris and then sudden cardiac death as a response to intense emotional stimuli is well known. A person may acquire a conditioned response to a life situation so that its reappearance or mere recollection results in angina pectoris. Furthermore, auricular fibrillation or flutter, premature contractions and paroxysmal tachycardia are frequent cardiac manifestations of anxiety states.[12] Palpitation dyspnea and precordial discomfort are among the most common cardiac complaints in psychic disturbances. The importance of neurocirculatory asthma in the Civil War, in World War I and to a lesser extent in World War II,[12a] is generally recognized. The electrocardiogram has been found[13] to change during psychic disturbances. These records are interesting and definite objective data indicating cardiac disturbances manifested particularly by change in the order of repolarization.

It is evident from the foregoing discussion that the somatic responses to psychic phenomena are well recognized. There are, however, several problems which deserve consideration. 1. Since psychic disturbances produce profound somatic reactions, often resulting in serious organic changes or even sudden death, the physician should routinely devote considerable attention to this problem in the proper management of his patient regardless of the disease state. 2. The existence of sustained anxiety states with prolonged somatic dysfunction with superimposed temporary but explosive psychic stress will result in serious organic disease. The importance and mechanisms of these phenomena are not well understood. There is a need to study these reactions in all organ systems. This is particularly important in the cardiovascular system, since its failure is the most common cause of death in man today, and it is becoming even more important as the life span increases. 3. The psychiatrist and psychologist are in great need of objective methods for approaching the problem of evaluating the mental processes. Because of the great reactivity of the cardiovascular system and especially the peripheral blood vessels to thought processes, the cardiovascular system is a good effector organ of psychic phenomena in both health and disease. In the past the approach has been mainly through the history and physical examination; and to a lesser extent through thermometric, electrocardiographic and ballistocardiographic and other studies on cardiac output. Some of these methods are cumbersome, impractical and often not informative. The extreme sensitivity and operative simplicity of the plethysmograph open a new approach to an understanding of the more subtle reactions. The accessibility and sensitivity of the vessels of the tips of the digits make such an approach practical, quantitative and objective. Reactions may be quantitated as to duration as well as degree. It is the purpose of this report to present studies of case histories and by use of a sensitive plethysmograph to demonstrate the potential as well as present value of plethysmography in man.

REPORTS OF CASES

The clinical data on 4 patients are presented first to illustrate certain facts related to psychosomatic phenomena concerning the cardiovascular system. Such problems as these are encountered frequently by all physicians.

Case 1.—J. C., a white man aged 44, entered the hospital complaining of a squeezing type of precordial pain which radiated into the left side of his neck and into the ulnar aspect of the left arm. The pain was not precipitated by exercise but occurred after a period of emotional excitement, particularly anger. The psychic disturbances resulting from worry about his ill wife and the problem of meeting the demands of his friends for new automobiles increased the ease with which the pain was produced. His family physician told him that he had angina pectoris. This was accepted fatalistically, thereby increasing his anxiety state and the episodes of pain. The entire physical examination and laboratory studies except the electrocardiogram (fig. 1) failed to reveal any abnormalities. He appeared apprehensive and rather anxious about his cardiac state. When he entered the heart station to record the electrocardiogram the extreme concern and anticipation of the nature of the results produced a typical anginal pain which lasted about ten minutes. The electrocardiogram (fig. 1 *A*) recorded during the period of pain showed changes in the S-T segment and the T wave, greatest in the V leads, typical of those observed in angina pectoris. Immediately after the pain disappeared another electrocardiogram was obtained which showed a reversion of the S-T segments and T waves to normal (fig. 1 *B*). The patient was then given an appointment to report to the laboratory for a plethysmographic study. The patient immediately began to experience some concern about the study. When dressing to come to the laboratory he became restless, irritable and anxious. He experienced episodes of mild anginal pain. By the time he entered the laboratory he was so disturbed psychically that he began to perspire freely and to show pallor and apprehension. He removed all of his clothing except his shorts and was allowed to remain alone. The

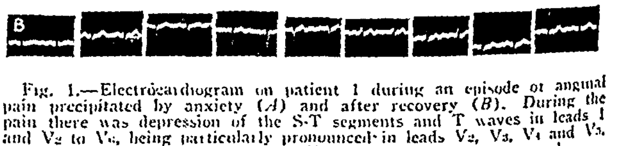

Fig. 1.—Electrocardiogram on patient 1 during an episode of anginal pain precipitated by anxiety (*A*) and after recovery (*B*). During the pain there was depression of the S-T segments and T waves in leads I and V_2 to V_6, being particularly pronounced in leads V_2, V_3, V_4 and V_5. After recovery from the pain the S-T segments returned to normal.

observers were soon called back because the patient rushed into the hall suffering from a severe attack of angina pectoris associated with a syncopal syndrome. An electrocardiogram recorded during the pain revealed the changes in the S-T segment and the T wave previously observed which are typical of those encountered in angina pectoris. Glyceryl trinitrate (his first experience) relieved the pain, and another electrocardiogram recorded after the pain had fully disappeared was normal. The electrocardiographic changes were similar to those noted previously (fig. 1).

The relationship of the psychic disturbances to the episodes of angina pectoris and the possible mechanisms were presented clearly and carefully to the patient. He readily became certain of the associations and realized that it was imperative for him to change his reactions to his problems if he was to improve his health. Drugs were not prescribed, although he was advised to carry glyceryl trinitrate. For the two month period following the instructions he has not had another episode of angina pectoris and has not employed any glyceryl trinitrate, an experience for which he is exceedingly grateful. His electrocardiogram has remained normal.

Comment.—The experience of this patient definitely indicates the relationship of the psychic state to cardiac function. The angina pectoris syndrome with the typical electrocardiographic findings (fig. 1) are objective evidence of such relationships. It is obvious that a vicious cycle was in progress in which the number and severity of the attacks of pain were increasing and in turn were increasing his anxiety state, which in turn increased the episodes of angina pectoris, etc. Drugs certainly were not the means for interrupting the cycle; this could only be accomplished by proper measures directed at the psychic disturbances. Previous therapy with drugs failed, while psychotherapy resulted in dramatic improvement. There is no doubt that the patient is still experiencing some psychologic disturbances, but they have not been severe enough to produce pain. It is possible, however, that they are producing subtle cardiac dysfunction which might have some influence on his cardiac state in the future. It is obvious that such phenomena can occur, but unfortunately are difficult to study. From a practical clinical point of view it is preferable to manage the patient as though they are occurring and therefore must be avoided by careful psychiatric management. The extreme sensitivity of the peripheral blood vessels to psychic disturbances is shown in the plethysmograms in figures 2, 3, 4 and 5.

Case 2.—E. B., a white man aged 63, was examined because of pressing precordial pain with radiation down the left arm. The onset was four months prior to admission. He had previously had extramarital intercourse with a neighbor. He had no difficulty until his wife learned of this affair, and during the ensuing weeks the characteristic clinical picture of angina pectoris would develop each time the subject was mentioned by his wife. In addition, the sight of the extramarital partner or recalling his experiences would result in pain and typical electrocardiographic changes of depression of the S-T segment and inversion of the T wave during the attack. Between episodes the electrocardiogram was normal. His severance of relations with the neighbor as well as an understanding of the correlation of all factors and the psychosomatic mechanisms at work both in the patient and in his wife resulted in a disappearance of the angina pectoris. At present, discussion of his past experiences produces no anginal pain or measurable peripheral vascular response.

Comment.—The relationship of the angina pectoris to the psychic disturbances is evident. The patient had developed a conditioned response to his friend such that sight of her or a mere thought of the conflicts involved and his wife's reactions would precipitate pain. As in the preceding patient it was not drug therapy that was indicated but rather psychotherapy. After adequate discussions of the problems with him and his wife, the patient has not had another episode of angina pectoris. Both patients have shown considerable improvement in general physical and mental health, and are now happy.

Case 3.—T. L., a Negro man aged 54, was seen because of chronic ulcers on the tips of the fingers. He was well until one and one-half years before admission. Chronic ulcers developed on two of his finger tips which healed slowly. Six months before admission ulcers developed on several fingers. He was examined by a number of physicians and was informed that he had leprosy. The decision to enter a leprosarium for complete isolation resulted in much family turmoil, quitting a job, terminating a happy family life and a great deal of other unhappiness. He entered the leprosarium, where the diagnosis was not confirmed and he was promptly discharged. After spending three weeks in another hospital without a diagnosis, he became anxious and resentful. When first seen in consultation at Charity Hospital he was resentful to the point of being noncooperative. During the interview the classic digital syncope of Raynaud's disease developed in two finger tips. The remainder were cyanotic. The characteristic changes in color followed. These reactions were discussed with the patient. He became considerably relieved to have a definite diagnosis finally established. The second interview was much less disturbing, and his attitude was one of cooperation. When the diagnosis of leprosy was mentioned, however, digital arterial spasm occurred and the resultant digital syncope appeared instantly. The typical changes in color followed. After the normal color had returned the diagnosis of leprosy was mentioned again with almost instantaneous digital syncope and the reappearance of the entire syndrome. During the succeeding two weeks he was seen on several occasions and every time that reference was made to the diagnosis of leprosy classic digital syncope followed immediately. The mention of any event or person associated with the previous diagnosis resulted in digital syncope.

The subject had been a successful Pullman porter for thirty years, but the increasing demands of patrons resulted in extreme resentment. Discussion of impatient and demanding patrons resulted in digital syncope.

Comment.—The relationship between emotional disturbances and peripheral "angina" is obvious in this subject. He demonstrated a conditioned response to his past experiences about leprosy so that reference to the disease, physicians or hospitals associated with that experience resulted in spasm of the digital arteries. The nature of the illness and the psychosomatic mechanisms at work have been explained to the patient. On subsequent visits there was progressively less reaction to discussions related to his past experiences. His progress on psychotherapy alone has been satisfactory and his entire outlook has changed.

Case 4.—R. S. H., a white male medical student aged 22, was seen because of short paroxysms of extreme hypertension. The presence of hypertension was noted on routine examination. Later the blood pressure was normal on repeated examinations. He once noticed that thinking of sexual intercourse would result in an elevation of the systolic blood pressure to 200 mm. or more. Within a period of a few minutes the blood pressure would fall to within normal limits. The subject learned that he could elevate his blood pressure voluntarily by thinking of sexual intercourse and tensing the muscles of the perineum.

Plethysmographic studies were obtained while the patient was given the Rorschach test (fig. 2 *C*). Throughout the test his blood pressure was elevated slightly and his pulse and alpha deflections were small, indicating vasoconstriction. He relaxed after this period and his blood pressure and pulse and alpha deflections returned to normal. He was asked to elevate his blood pressure again. Within a period of one minute his blood pressure rose from a normal level to 250 systolic and 150 diastolic. The pulse deflections were small and the alpha deflections practically disappeared, indicating pronounced vasoconstriction. His expression became apprehensive; his pupils dilated and a severe bitemporal headache occurred. Within a short time the blood pressure returned to normal. The observation was interrupted by the subject's having to urinate, although the bladder was emptied one hour earlier. After the hypertension there was a large quantity of almost colorless urine of low specific gravity, whereas one hour earlier the urine was a normal amber color.

Comment.—The observations in this case further indicate the relationship of the mental processes to the state of the blood vessels. By an erotic thought the subject could purposely elevate his blood pressure. The extreme vasoconstriction is indicated by the small pulse and alpha deflections and the degree of hypertension. It is interesting that the process of relaxation was also under voluntary control, although a slightly longer time was required for the blood pressure to return to the resting level. The vasoconstrictor response was immediate and consistent. The effect on the kidneys was striking. The large volume of hyposthenuric urine is attributable to the increase in filtration pressure, probably due in part to constriction of the efferent arterioles of the glomeruli. The dilatation of the pupils indicates a diffuse sympathetic stimulation. Repeated reactions of this magnitude may be expected to result in organic vascular disease.

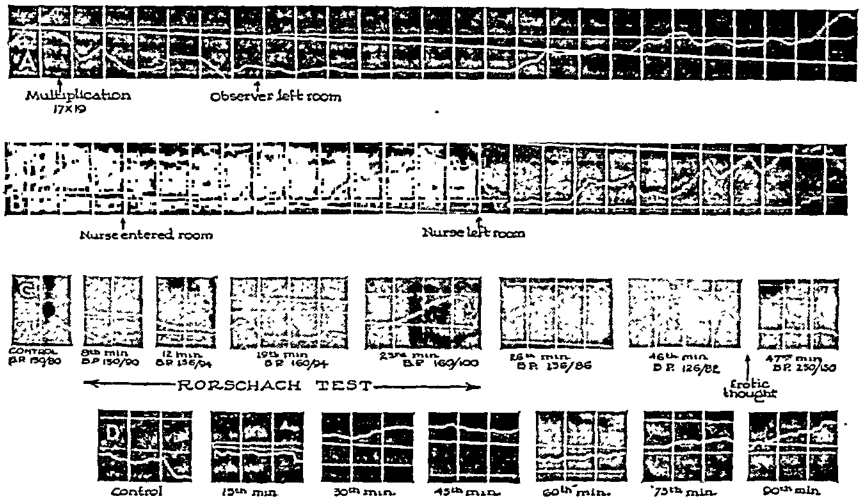

Fig. 2.—Plethysmograms obtained from the tip of the index finger of several subjects. *A*, prolonged vasoconstriction following a problem in multiplication by a normal subject. The pulse and alpha deflections are small indicating pronounced vasoconstriction. *B*, reaction to the entrance of a nurse into the normal subject's room. Both entrance and departure of the nurse resulted in vasoconstriction. *C*, plethysmogram on patient 4, who was able to produce decided hypertension voluntarily by an erotic thought. The control tracing shows normal pulse and alpha deflections. During the Rorschach test there is obvious vasoconstriction, the pulse and alpha deflections being small. The twenty-sixth and forty-sixth minutes demonstrate normal pulse and alpha deflections. The last plethysmogram recorded during the intentionally produced hypertension shows pronounced vasoconstriction. *D*, plethysmograms on patient 1, who had an episode of angina pectoris precipitated by an anxiety state. Plethysmograms taken at fifteen minute intervals show vasoconstriction throughout the entire period of observation. At no time during the study did the subject become relaxed. The patient had anginal pain during the early portion of the observation.

PLETHYSMOGRAPHY

During the course of plethysmographic studies on normal subjects and patients with various types of cardiovascular disease states, it became evident that the peripheral blood vessels are easily influenced by psychic disturbances. The development of a practical type of plethysmograph[14] has made it possible for others to search these problems. Psychosomatic studies directed at the peripheral blood vessels are important because of the possible relationship to disease states related to the cardiovascular system as well as to the psyche. Furthermore, it will be shown that plethysmography offers an objective approach to many problems in psychology and psychiatry.

The relationship of changes in the volume of the vascular bed to variations in the psychic state is not a new observation. It is only necessary to recollect the cardiovascular reactions associated with syncope produced by fear, a phenomenon as old as man himself. The studies of Burton,[15] Goetz,[16] Hertzman and Dillon,[17] Neuman and others,[18] Gottschalk,[19] Burch and coworkers[20] and others have shown the relationship of the behavior of the peripheral blood vessels to psychic function. It has been suggested[21] that a correlation of the five types of volume deflections (pulse, respiratory, alpha, beta and gamma) of the peripheral blood vessels may serve as an index of emotional states and types of personality. The exact patterns of the volume deflections related to the psychic states have been only partially observed.

It is well to remember that the peripheral blood vessels offer something somewhat unique in the approach to psychosomatic problems: (1) the peripheral vessels are extremely sensitive to mental processes of the conscious and subconscious levels; (2) they are readily accessible and (3) a sensitive and quantitative method (the plethysmograph) makes it practical to observe small and sudden vascular reactions. The peripheral blood vessels can serve as a useful tool as effector organs in psychosomatic phenomena.

[21] Burch, Cohn and Neumann.[7] Neumann, Lhamon and Cohn.[18a]

To illustrate the psychosomatic relationships of the peripheral blood vessels and psychic processes certain plethysmograms were recorded. Subjects were made to rest in bed in an air-conditioned room (not necessary for all types of studies, however), with temperature and relative humidity approximately 78 F. and 50 per cent, and plethysmographic recordings of the changes in vascular volume of the tips of the index finger and/or second toe were made as previously described.[11] The observation room was especially designed to reduce psychic disturbances to a minimum.[18b] The subjects studied were young men and women (medical students) who were normal or patients with known abnormal psychiatric states, usually anxiety neurosis. During the course of the recording of the plethysmograms psychic disturbances were produced by various methods, including entrance into the room, frowning at the subject, questioning the subject, dropping a book in an adjacent room, buzzing a buzzer, loud talking, multiplication of numbers, etc.

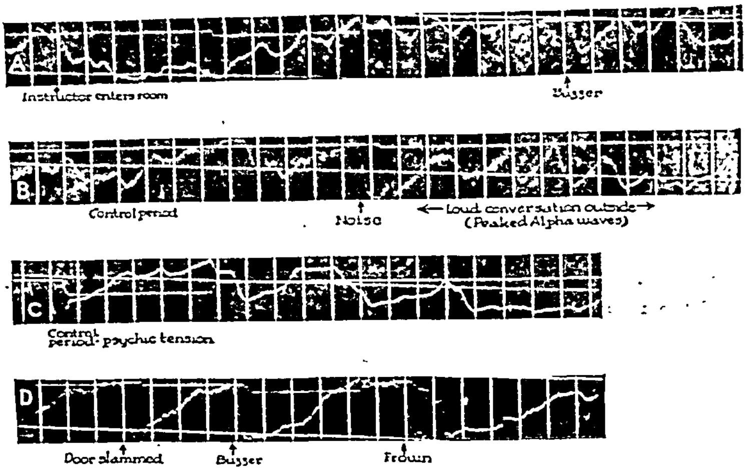

Fig 3.—Plethysmograms obtained from the tip of the index finger of normal subjects. *A*, reaction to the subject's instructor entering the room with resultant small pulse and alpha deflections indicating vasoconstriction. The peaked alpha deflections which followed suggest incomplete relaxation. The sound of a buzzer in the observation room produced vasoconstriction again. *B*, normal alpha waves during the control period followed by vasoconstriction in response to a noise in the adjacent room. Again, the high peaked alpha waves indicate incomplete relaxation, probably related to loud conversations outside. *C*, plethysmogram of a subject who was anxious at the onset of the observations. The pulse and alpha deflections are small throughout the record, indicating vasoconstriction. *D*, the same subject as *C*, fifteen minutes later. The pulse deflections in the first portion of the record are of normal size and indicate that a state of relaxation had been reached. Noises (door slammed across the hall and buzzer) resulted in vasoconstriction again with immediate return to the resting stage. When the observer frowned at the subject the reaction was more intense (smaller pulse and alpha deflections) and more prolonged.

All test stimuli evoked demonstrable reactions; i. e., reduction in the volume of pulse deflections and in total volume of the part. In addition, there were changes in the alpha deflections. They became smaller, more irregular and exhibited a more rapid rate of change than in a normal relaxed subject (fig. 3*B*).

Other determinants of the degree of the reaction are the nature and intensity of the stimuli. For example, informing a student that he has failed an examination produces a greater and more prolonged reaction than the pain of a pin prick. The degree of reaction can be measured in terms of the percentage change in the volume of the vascular bed and the duration of these changes.

Many patients have been observed who did not achieve relaxation (that is, they were in a state of psychic tension) during the entire period of observation (figs. 2*D* and 3*C*). As would be expected, the degree of reaction occurring in a person with preexisting vasoconstriction is less than that which occurs in a subject with vasodilatation before application of the stimulus (figs. 4*C* and 4*D*).

Furthermore, the failure of a person to become mentally at ease under conditions conducive to a state of relaxation of the peripheral blood vessels becomes recognizable through the medium of the plethysmogram in that the volume of the pulse and alpha deflections remains small and the character altered. An example of this is illustrated by figure 2*D*, which shows small alpha and pulse deflections throughout an entire period of observation of approximately two hours. Subjects who have been placed in a state of mental unrest by certain psychic influences to which they are rather sensitive will show a prolonged reduction in volume of alpha and pulse deflections. An example of this is shown in figures 3*A* and 4*A*, in which a student's instructor remained in the observation room. During this time the peripheral blood vessels reflected his psychic disturbances. After the instructor left the room the subject soon became mentally at ease and his pulse and alpha waves returned to normal volume and character (figs. 3*A* and 4*A*). These vascular reactions to mental unrest are further demonstrated by the fact that the mental processes concerned with simple multiplication resulted in a considerable and sustained decrease in the volume of alpha and pulse deflections (figs. 2*A* and 5*A*). These deflections did not return to normal until the process of multiplication had been completed. However, they again suddenly reduced in volume when the subject was seized with the idea that he had made an error in the calculations. When reassured of the accuracy of the multiplication, relaxation of the blood vessels followed (fig. 5*A*).

A self-induced psychic disturbance with pronounced vasoconstriction and hypertension was produced by one subject. This resulted in tachycardia, elevation of blood pressure to 250 systolic and 150 diastolic, marked diuresis and hyposthenuria and an intense bitemporal pain. These changes were brought about by an erotic thought. The plethysmogram was characterized by a considerable reduction in the volume of peripheral vessels of the finger and toe tips with the associated reduction of the pulse and alpha deflections (fig. 2C). These reactions were transient, being produced when the thought was brought to conscious levels and disappearing when the thought was dismissed.

The rapid and acute peripheral vascular reactions to minor stimuli were produced in a number of subjects. These are summarized in figures 2, 3, 4 and 5. It can be seen that there was a rapid emptying of the blood vessels of the fingers and toes evidenced by a decrease in total volume of the part as well as in the volume of pulse and alpha deflections when the stimuli were applied. For example, such stimuli as a noise, frowning at the subject by the observer and a pin prick resulted in demonstrable vascular responses.

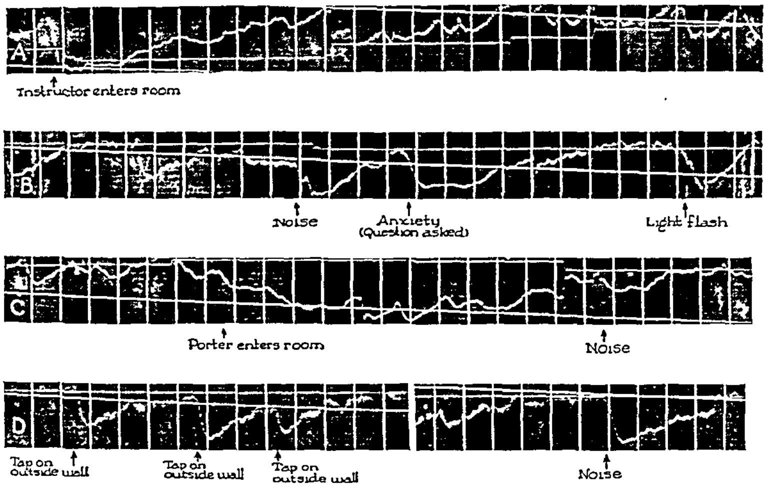

Fig. 4.--Plethysmograms obtained from tips of the incex finger and second toe *(C)* of normal subjects. *A*, decided reaction to the subject's instructor entering the room. The pulse and alpha deflections are small. The high peaked alpha waves in the last portion of the record indicate failure to return to the degree of relaxation present initially. *B*, reaction to noise, anxiety and light flash. The anxiety was a result of referring to an examination which the subject had recently taken. The vasoconstriction produced by the anxiety was of longer duration than the response to noise or light. *C*, plethysmogram obtained from the tip of the second toe of the subject in *B*. The first portion of the record shows normal pulse and alpha deflections. A porter's entrance into the room resulted in vasoconstriction and small pulse and alpha deflections. This reaction continued throughout the record. When a second stimulus (noise) was applied to a person already in a state of vasoconstriction little further reaction occurred. *D*, reactions to the same stimulus repeated at frequent intervals in subject of *B* and *C*. There was less reaction to the last stimulus, a sort of " tachyphylaxis." The reaction to noise by the same subject when the vessels were relaxed resulted in pronounced vasoconstriction.

GENERAL COMMENT

From the foregoing considerations, it is obvious that the cardiovascular system is responsive to psychic stimuli. This is true for both the central and the peripheral portions. In the past, these reactions have been followed by relatively limited methods; namely, the electrocardiograph, determination of blood pressure and general clinical observations. The plethysmograph increases our armamentarium. From the plethysmographic studies presented it becomes evident that the peripheral blood vessels of man are in a constant state of turmoil produced by the many variable environmental stimuli. For example, such simple disturbances as the entrance of a person into a subject's room will produce vasoconstriction. It then becomes a problem of differentiating the aspects of those reactions which are of fundamental nature in maintaining physiologic health from those which produce subtle but repeated wear and tear ultimately resulting in cardiovascular abnormalities.

From the point of view of the psychiatrist, these peripheral vascular reactions observed plethysmographically can serve as an objective and quantitative index of certain psychiatric and psychologic states. As mentioned previously there is a need for objective methods of following mental processes. The peripheral blood vessels serve as a sensitive effector organ, and a sensitive plethysmograph[14] as a simple and practical apparatus for recording these reactions.

It is evident from the case histories described that in the clinical management of a patient, particularly the patient with cardiovascular disease, it is imperative that the physician devote considerable time to an analysis of psychiatric problems. In many instances it will be found that it is psychotherapy rather than drug therapy which will produce desired clinical results. To neglect psychotherapy and employ drug or surgical therapy would result in therapeutic failure. Even though psychiatric analysis is time consuming, the rewards in therapeutic results justify a careful study. It is impossible to overemphasize the role of anxiety states and other psychiatric problems in the management of the patient with cardiovascular abnormalities.

SUMMARY

The cardiovascular system is particularly susceptible to psychic disturbances and it is the most commonly involved effector organ.

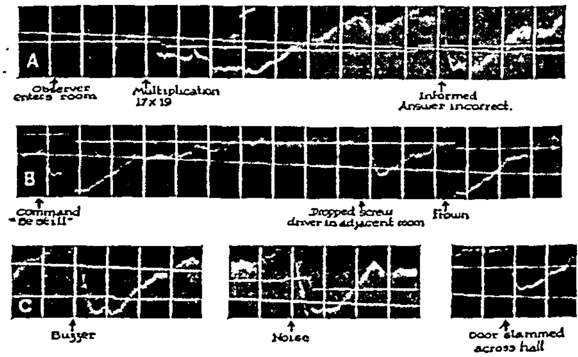

Fig. 5.—Plethysmograms obtained from tip of index finger in 3 normal subjects. *A*, the reaction to an observer entering room was slight. Considerable vasoconstriction resulted from a problem in multiplication. After the problem was completed, relaxation followed. When the subject was informed that the answer was incorrect an immediate vasoconstriction recurred. *B*, vasoconstriction resulted from a gruff command, "Be still!" *The reaction to a frown was approximately of the same* duration and intensity. The response to noise was short and not so great. *C*, vasoconstriction produced in 3 subjects by different stimuli.

The central (cardiac) effects are numerous and include (1) increased cardiac output, (2) mechanistic disturbances, (3) electrocardiographic changes, (4) angina pectoris and (5) even sudden death.

The peripheral vascular system is extremely responsive to the thought processes and emotional stimuli, and this portion of the cardiovascular system is readily accessible for qualitative and quantitative study.

A simple, accurate and quantitative method for study of the more subtle reactions has been described. The degree and duration of the vascular responses reflect the intensity of the emotional stimuli. Tense, unrelaxed subjects may be identified by the character of their plethysmogram. The potentialities of the plethysmograph in psychiatric evaluation are great. Its application as a new avenue of objective approach in psychiatry deserves further investigation.

Four case histories have been presented to illustrate the pronounced effect which disturbances in the psyche exert on the cardiovascular system. The need of psychiatric evaluation and the use of psychotherapy in the proper management of cardiovascular problems has been emphasized.

ABSTRACT OF DISCUSSION

Dr. George A. Wolf Jr., New York: I can add nothing to what has been observed, but I would like to speculate a little on the possibilities of such a method. It illustrates nicely that when we consider our patients to be in the basal state, during cardiovascular experiments with people walking in and out of the room and lights going on and off, they are not truly in the basal state, as far as their reactibility is concerned. One aspect of this problem is the reactibility of the same person at different times and the reactibility of different persons. In this regard what is the relationship of hypertensive to normal persons, early in their lives prior to the development of hypertensive disease, when hypertension becomes moderately developed and, later when they have advanced hypertension with outright vascular disease? A group of workers at the Rockefeller Institute have pursued this question. Would this method be of any value in deciding whether there is a real difference in the reactibility of peripheral blood vessels in these various phases of hypertension? As far as the psychologic phenomena are concerned, it would be of interest to determine whether a specific emotional state could be correlated with the reactibility of the blood vessels and the degree of reaction, inasmuch as the method described is a quantitative one. These are some of the things which might be pursued by this instrument. As Dr. Burch pointed out, a way to make progress in this field is to explore the physiology of so-called emotional states with every instrument available and attempt to associate the physiologic changes with the emotions.

Dr. Mandel E. Cohen, Boston: Little could be added to the description of the plethysmograph and the observations on it. Dr. Burch has conquered most of the difficulties in accuracy that have gone with this type of recording, with this new apparatus. This leaves us free to discuss the problem of the stimulus in this type of study and the general problem of drawing conclusions from this type of experiment. It is important to examine the general aspects, since many unproved assertions and broad generalizations are found in the medical field now called by some psychosomatic medicine. In studying the effect of an emotion-provoking stimulus on a measurement of physiologic function, it is important to ask whether the emotion-provoking stimulus is specific and crucial. But does any stimulus such as change of posture or slamming the door cause the same response? If talk stimulus causes the response, does any talk do it or must some special talk such as about special problems do it? For instance, we heard a report of a patient's changes in blood pressure associated with special problems about the patient, but in that report the author had neglected to say what happened if one just talked about anything. It is good to use plain language and not pretentious psychologic talk. Finally, we must be careful about conclusions. If we attempted to say that emotions cause hypertension because they cause blood pressure to go up—well, putting the hand in ice water also causes the blood pressure to go up, and it would be just as plausible to say that ice water causes hypertension. If experiments are so difficult to draw conclusions from, how much harder is it to interpret a patient's history to connect emotion-provoking situations with symptoms of disease? We must know whether the reported experience is accurate. Did it relate in time to the symptom? Did the experience cause the disease, or was it merely one of many factors that may have provoked symptoms? Or did the disease itself lead to the emotional disturbance? This aspect of medicine is still a mass of unproved assertions. Our attitude toward work in this field should be the same as in other parts of medicine. We should not neglect the possibilities, nor should we be gullible, to accept without adequate evidence, sufficient cases or adequate controls speculations and conclusions related to the reaction or emotion-provoking stimuli to disease. Even if the magical word "psychosomatic" beckons us, we can still demand cold facts before accepting the conclusions.

Dr. George E. Burch, New Orleans: As stated, this was not an organized attempt to solve the characteristic plethysmographic patterns that might be specific for any one type of psychic disturbance. We have always been impressed by the ease with which these vascular reactions occur after some of the minor, ordinary and everyday psychic experiences. We feel that the problem of plethysmography is essentially where electrocardiography was about 1900. There are many vascular patterns which have not been described. There is a great opportunity for the psychiatrist to approach many of his problems through the peripheral blood vessels as organs reflecting psychosomatic phenomena.

MANAGEMENT OF PROTEIN DEFICIENCY IN SURGICAL PATIENTS

Intravenous and Intrajejunal Injections

JOHN D. STEWART, M.D.
HARRY W. HALE Jr., M.D.
and
SIDNEY M. SCHAER, M.D.
Buffalo

Though protein nutrition is important in any field of medicine it is of special concern to the surgeon. The surgeon is often charged with the care of a depleted patient who must undergo a major surgical procedure as part of his treatment. In many instances obstructing or inflammatory lesions of the gastrointestinal tract preclude adequate oral alimentation. Superimposed on an accumulated nitrogen deficit may be losses of protein through draining wounds and sinuses, into areas of inflammation and into traumatized tissues, and losses from hemorrhage; the "reaction of injury" involving an ill understood increase in the rate of protein catabolism often inevitably complicates the problem for the surgeon. Furthermore, the hazards of protein deficiency during convalescence from surgical operation have come into clearer recognition as the subject has received closer study.

Despite the fundamental contributions of numerous investigators of protein metabolism and the adaptation of basic facts to clinical problems, various questions remain unanswered. For example, the possible increase in the need of specific amino acids or amino acid mixtures as occasioned by specific diseases is an obvious question which might repay study by qualified investigators. The present paper is concerned with some of the more practical aspects of protein nutrition in surgical patients. For the patient who cannot eat and who needs

Read before the Section on Surgery, General and Abdominal, at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1947.

six months as the sole source of food, and weight and sense of well-being were maintained. For many of our patients intravenous and intrajejunal alimentation are used concurrently.

A satisfactory mixture for intrajejunal feeding must fulfil certain requirements, and in our judgment these may be set down as follows:

1. The mixture should be complete and should supply in adequate amount the elements of the normal diet.
2. It should be fluid enough to drip by gravity through a small catheter (no. 16 F.) without undue sedimentation.
3. It should be neutral in reaction or approximately so.
4. It should contain enough colloid to protect the intestinal mucosa against irritant "salt action."
5. It should be inexpensive and easily prepared.
6. It should be capable of being varied to meet individual needs.
7. It should yield a low residue during digestion and absorption.
8. It should be easily digested and absorbed.
9. It should keep at least forty-eight hours in the refrigerator.

A formula which meets these criteria reasonably well and which we have used for the last six years is detailed in table 3.

TABLE 3.—*Formula for Intrajejunal Feeding*

		Salt Mixture	
Water	2,000 cc.		
Sucrose	300 Gm.		
Casein	200 Gm.	$CaCO_3$	20.0
Dried yeast	30 Gm.	$NaH_2PO_4 \cdot H_2O$	16.0
Trypsin	5 Gm.	KCl	28.0
Vitamin C	100 mg.	$MgCO_3$	6.0
Halibut liver oil	1 Gm.	Na_2CO_3	6.0
Vitamin K	4 mg.	FeAmm. citrate	6.0
Salt mixture	10 Gm.	NaCl	18.0

In the preparation of the mixture the casein is added slowly to the water while being brought into even solution with the help of a mechanical mixer. The casein is obtained in 25 (9 Kg.) or 50 pound (22 Kg.) lots, with a considerable saving in cost. The fat, and hence the caloric value, of the mixture can easily be increased by the addition of olive oil, cream or corn oil as indicated.

Chemical analysis of this mixture gives the following results:

Average total weight	2,543 Gm.
Average total volume	2,395 cc.
Percentage of moisture by weight	78
Percentage of solids by weight	22
Percentage of dry ash by weight	0.75
Specific gravity	1.068
Total protein content (nitrogen × 6.25)	196.5 Gm.
Total chloride content	3.9 Gm.
Total sodium content	
determined directly on sample	4.1 Gm.
determined on ash	4.1 Gm.
Total calcium content determined on ash	1.1 Gm.
Total phosphorus content determined on ash	4.7 Gm.
Total potassium content determined on ash	1.9 Gm.
pH (fresh and after four days at 4 C.)	6.2
Total fat content (ether 1-petroleum ether 1)	5.08 Gm.

This mixture is given each day by gravity drip, preferably continuously over a twelve hour period. If the patient is ambulatory the administration can be carried out during the night without disturbance of his sleep. If the solution is injected intermittently care must be used not to instil too much at one time, since distention of the jejunal loop, nausea or cramps and diarrhea may occur. Three or 4 ounces (90 or 120 Gm.) instilled into the jejunostomy catheter every half hour during the day may be employed, and in many instances the patient learns to do this himself, with a consequent saving in nursing time. Continuous administration of the formula by gravity drip during the night is the method to be preferred, as the patient is thus freed for studies or for ambulation during the day. Occasionally the feedings provoke diarrhea, in which event temporary suspension of the method or reduction in the amount administered together with injection of paregoric into the jejunostomy gives relief. In other instances the mixture is found to be constipating.

Our experience with intrajejunal alimentation has included observance of cases of esophageal carcinoma treated later by resection, and particularly of cases of carcinoma of the stomach in which there was involvement of the cardiac end. Patients with pyloric obstruction due to carcinoma or ulcer and patients with obstructing or bleeding duodenal ulcer have at times been prepared for definitive gastric resection by intrajejunal feeding. The jejunostomy opening may be closed from within at the time of gastric resection if technical considerations so indicate and if the patient's need for such feeding has been relieved. In cases of pyloric or duodenal obstruction we do not advise reinjection into the jejunostomy opening of aspirated gastric secretions, as such fluid may be laden with bacteria and its volume interferes with the intrajejunal administration of the more nutritious formula.

In cases of obstructive jaundice and hepatic damage there is reason to believe that the high protein, low fat mixture described may be beneficial, and clinical experience with such cases confirms the belief. The method has been used chiefly for feeding during convalescence after pancreaticoduodenectomy, the jejunostomy having been done at the time of the definitive operation. It is undoubtedly desirable to have the patient take such a dietary mixture before as well as after pancreaticoduodenectomy, and this can be accomplished by feeding by drip through an inlying nasogastric tube before operation. It has seemed to us technically undesirable to complicate the problem of resection of the head of the pancreas and duodenum by a previously performed jejunostomy. There is a place for this method in cases of complicated stricture of the common duct with recurring cholangitis and hepatic damage,[4] and the usefulness of intrajejunal feeding in patients with malfunctioning gastroenterostomy stomas—fortunately a less common problem nowadays—has been pointed out.[5] The occasional case of postoperative duodenal fistula likewise may constitute an indication for intrajejunal feeding.

In conclusion it may be stated that:

(1) in the practical matter of meeting protein needs of surgical patients intravenous infusions of amino acid mixtures with dextrose and intrajejunal injection of a more complete dietary mixture are safe and effective and (2) such therapy is important before as well as after operation and it is frequently essential for the success of major surgical procedures.

ABSTRACT OF DISCUSSION

DR. I. S. RAVDIN, Philadelphia: More work of the type which Dr. Stewart and his group are doing is necessary before the best mixtures for oral or parenteral use can be available. It is highly likely that under varying needs a single solution will not adequately answer all the requirements to an optimal degree. Most of the nutritional deficiencies in man are complex deficiencies.

involving more than a single dietary component. In correcting a nutritional deficiency by any route, it is important to provide not only a balanced ration but also sufficient calories. We have talked too freely about the essential amino acids. It has been shown by Rose that they are essential for the growth of the rat and that when given in adequate amounts to man as the sole source of exogenous protein along with other dietary components a positive nitrogen balance can be achieved. Under certain conditions of disease or injury, when endogenous protein metabolism is disturbed, the problem is probably not so simple. While intravenous injections are often necessary as the sole source of dietary intake, it should be remembered that when the oral, orogastric or jejunal method of feeding can be used it is extravagant and wasteful to use the intravenous route. Riegel and her associates, working in our laboratories, have found that a positive nitrogen balance can be achieved in patients who have undergone a major operation when 0.3 Gm. of nitrogen and 30 calories per kilogram of body weight are given by any oral method but that nearly twice as much nitrogen is required with the same caloric intake when the intravenous route is used. The data of Madden are essentially in agreement with those of Riegel. The aim of any feeding program must be to achieve a positive nutritional balance. This is most easily and least expensively obtained by one of the direct alimentary methods. Dr. Stewart's work substantiates this statement. While it is possible to achieve a positive nitrogen balance by intravenous therapy if this is carefully controlled, it frequently is not achieved. To the extent to which a positive nutritional balance is achieved in patients, a corresponding decrease will be observed in the complications of anesthesia and operation.

Dr. Robert Elman, St. Louis: I have some data on patients who were kept on total intravenuous feeding after abdominal operation on a daily intake of 100 Gm. each of "amigen" and dextrose. In patient, after an extensive resection for jejunal ulcer, there was almost positive nitrogen balance. The net loss on one or two days was only 2 or 3 Gm. Patient, with injections of dextrose alone, would have shown a loss of at least 12 to 20 Gm. of nitrogen a day. In this patient I resected multiple intestinal fistulas and part of the abdominal wall, with primary anastomosis and closure. Note the positive nitrogen balance on six postoperative days even though the nitrogen intake on four of those days was very small (6 Gm.). Data were obtained during seventy-six days after serious abdominal operations. Caloric intake, because of the administration of 100 Gm. of dextrose, was 400. "Amigen" intake was 100 Gm. Note that the average loss of nitrogen was only 3.7 Gm. a day. Anyone who has studied these cases realizes that under the usual regimen or dextrose alone the loss varies between 10 and 20 Gm. of nitrogen a day. Thus it is clear that nitrogen balance or, at the worst, minimal losses will occur in many cases after operation with the daily injection of only 100 Gm. of hydrolyzed protein even when the caloric intake from dextrose is restricted to 400.

BRONCHOGENIC CARCINOMA.—The treatment of bronchogenic carcinoma consists of pneumonectomy with extirpation of the mediastinal nodes. It is our belief that it is just as essential to perform a pneumonectomy and to completely extirpate the mediastinal nodes in a patient with a bronchogenic carcinoma as it is to remove the entire breast and axillary nodes in a patient with carcinoma of the breast. Whereas there are some surgeons who believe that lobectomy is indicated in certain cases of malignant disease of the lung, we are of the opinion that lobectomy has little if any place in the treatment of primary malignancy of the lung. Only by the radical pneumonectomy with complete extirpation of the mediastinal nodes can good results be expected in the treatment of these neoplasms.—Ochsner, DeBakey, and Dixon, J.; Primary Malignancy of the Lung, *South Dakota Journal of Medicine*, February 1948.

RAPID TEST FOR THE DEMONSTRATION OF SICKLE CELLS AND ITS CLINICAL SIGNIFICANCE

KARL SINGER, M.D.
and
SIDNEY ROBIN, M.D.
Chicago

The various factors which cause or influence the phenomenon of sickling red cells are still poorly understood. This peculiar behavior of certain red blood corpuscles seems to be a racial characteristic, confined exclusively to the Negro, although a few cases of sickle cell anemia in white persons have been reported.[1] From what is so far known, one must assume that sickling will only occur in the presence of a fundamental alteration in the physicochemical structure of the erythrocyte, since normal cells cannot be induced to undergo such a change in shape. This constitutional structural defect is already demonstrable in the hemoglobin-containing erythroblast.[2]

Hahn and Gillespie [3] made the significant discovery that distortion of the susceptible corpuscles into sickle cells will only take place if the hemoglobin contained in the cells is in the reduced state. Presence of oxyhemoglobin or carbon monoxide hemoglobin prevents the sickle cell phenomenon. If sickled cells are exposed to a sufficient oxygen concentration they revert immediately to their original form. By means of a gas chamber into which susceptible red cells are suspended in a hanging drop of saline solution, the erythrocytes can be transformed at will by admission of alternating streams of carbon dioxide or oxygen into the chamber. Although this ingenious method is too elaborate for routine clinical use,[4] the principle established by it—namely, that sickling will develop only in the presence of reduced hemoglobin—forms the basis of all other tests which have been advocated for the detection of the sickling trait.

Diggs and Pettit [4] in 1940 compared all recommended technics and concluded that the moist stasis test of Scriver and Waugh [5] is the most reliable and the most practical method. In this test anoxia is produced by placing a rubber band around the proximal portion of a finger. Stasis is maintained for five minutes. Then the finger is punctured in the usual way and a drop of the dark blood is sealed under a cover slip as rapidly as possible. The greatest disadvantage of this method is the unavoidable partial reoxygenation of the hemoglobin due to exposure to air when the blood is transferred from the finger to the slide.

Since mature red cells do not themselves consume oxygen, reduction of the oxyhemoglobin must necessarily depend on the oxygen consumption of the variable number of nucleated red cells, reticulocytes and leukocytes available in the sealed preparation. It is therefore not astonishing that sickling may sometimes be demonstrable only after forty-eight to seventy-two hours.

Rather recently Neuda and Rosen [6] reported a new rapid method for the demonstration of the sickling phenomenon. By mixing blood with a broth culture of a saline extract of human feces they could elicit the characteristic distortion of the susceptible erythrocytes within the first hour after preparation of this mixture. They attributed the enhancing of the sickling process to a—hypothetical—cell-damaging factor of enzymatic nature which is supposed to be present in the stool extract.

In this paper we want to describe a method which induces the sickling process in five to fifteen minutes with invariable regularity. The test is based on the principle of suspending the suspected erythrocytes in a culture of nonpathogenic bacteria and then sealing the preparation. The living organisms consume oxygen rapidly and also give off carbon dioxide, thus creating the most favorable conditions for the detection of sickling tendencies.

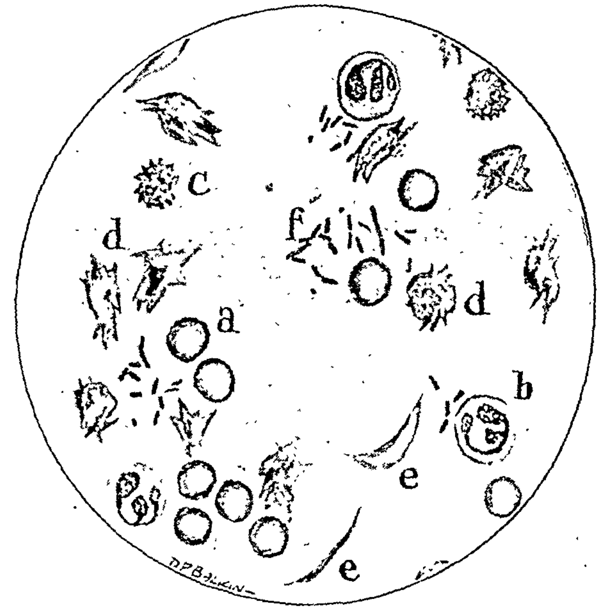

Fig. 2.—Rapid test positive in result: (*a*) red cell; (*b*) white cell; (*c*) crenated red cell; (*d*) oat cell; (*e*) sickle cell; (*f*) bacteria.

TECHNIC OF THE RAPID BACTERIOLOGIC TEST FOR THE SICKLING PHENOMENON

The reagent used in performing the rapid bacteriologic test is a turbid culture of Bacillus *subtilis grown* in dextrose veal broth. B. subtilis was selected because of its high oxygen consumption and its established nonpathogenicity. Cultures of Escherichia coli and Aerobacter aerogenes were found to be almost equally effective. An active reagent was usually obtained by inoculating 4 cc. of broth with a loop of pure subtilis culture grown on an agar slant medium. The broth was then kept in the incubator for several hours at a temperature of 37 C. When inoculation was performed in the late afternoon, the test fluid was ready for use next morning. During the day the broth culture was allowed to stand at room temperature in order to avoid overgrowth, which easily occurs when the culture is kept in the incubator too long. Such an improperly prepared reagent is characterized by diminished or absent motility of the bacteria. For this reason ripening of the culture over the weekends was also obtained at room temperature. Perpetuation of the bacterial reagent can be accomplished by placing each day a few drops of the used broth culture into fresh broth medium. However, that cannot be continued indefinitely, since the bacteria become increasingly sluggish and show signs of deterioration after a few days. Reactivation of the reagent culture must be performed at least once a week by inoculating from an agar slant. Before each performance of the rapid test one must be sure to have an active reagent. Such an active test fluid is characterized by gross turbidity, absence of any precipitate or pellicle in the culture tube and microscopically by numerous actively motile bacteria. Furthermore, hemolysis of the red cells in the preparation within thirty minutes to two hours is also indicative of an effective culture. Although the necessity of caring for the perpetuation of the culture reagent in order to have it ready for use at all times represents the "weak point" of the rapid test, actually it causes little trouble if properly performed and requires but a few minutes per day.

Blood may be obtained by puncturing the finger in the usual way, or oxalated venous blood can also be used. If the blood sample has been kept in the refrigerator, it should be warmed before the test is performed, as chilling of the blood causes a prolongation of the reaction time.

The actual performance of the test is simple. One drop of blood and 1 drop of culture are mixed on a clean slide by means of a glass rod and then covered with a cover slip. The preparation should be free from air bubbles. The edges of the cover slip are sealed with paraffin and the slide is then placed into the incubator at 37 C. for five minutes. If the reading of the preparation shows no presence of sickling tendencies, the slide is again placed in the incubator for ten minutes, and then reevaluated. If after fifteen minutes no characteristically distorted erythrocytes are noted, the result of the test can safely be reported as negative.

However, one must keep in mind that the reaction time in this technic depends on three factors: the "activity" of the test fluid, the temperature and the intracorpuscular forces responsible for the sickling phenomenon. If the first two conditions are kept at an optimum, the third variable is of surprisingly little significance. In this respect the bacteriologic test differs remarkably from the moist stasis method, in which the inherent sickling tendencies of the red cells play probably an important role.

---

[6] Neuda, P. M., and Rosen, M. S.: Preliminary Report on a Rapid Method for Diagnosing Sickle Cell Disease, J. Lab. & Clin. Med. **30**: 456-458 (May) 1945.

Reading of the preparations should not present any real difficulties if the oil immersion lens is used. Figure 1 visualizes a test which is negative in result. In this preparation the red cells are often crenated because the test fluid is not isotonic. In a test with positive result (fig. 2) one may see either the true sickle cells (fig. 2*c*) or cells which are not crescent shaped but look very distorted on account of variable filaments and finlike appendages which protrude from the surface of the cell (fig. 2*d*). We have applied the designation oat cells[7] to all these noncrescentic cells. They can probably be considered as precursors of the true sickle cells. Their presence is absolutely pathognomonic for the sickle cell phenomenon. It is perhaps conceivable that some of the oat cells may be confused with crenated erythrocytes. However, the protrusions of the crenated cells are equally spaced and of equal length, whereas those of the oat cells are irregularly spaced and of variable length and diameter.

The results obtained with the rapid test were arbitrarily graded as (1) negative: no oat or sickle cells present; (2) doubtful: 1 or 2 oat cells per oil immersion field and (3) positive: grade 1 when 3 to 5, grade 2 when 5 to 10, grade 3 when more than 10 unmistakable oat cells were present per oil immersion field, grade 4 when several or numerous crescentic erythrocytes were observed per oil immersion field. Interestingly we have not come across a preparation which has to be graded as doubtful or belonging to grade 1. After fifteen minutes' observation time the results of the test are therefore very distinct.

One hundred and sixteen Negroes were examined with the bacteriologic test, and at the same time a control was set up either with the moist stasis method or, when venous blood was used, with an ordinary sealed moist preparation. Of these tests thirty-eight were positive in result. The material selected for these tests comprises ward patients and also patients attending the Hematology Clinic, and the results are therefore not representative for the occurrence of the sickle cell trait in the Negro population of Chicago. Of the 38 patients giving a positive result, 14 had more or less decided sickle cell anemia. This diagnosis was based on the clinical picture, on determinations of the reticulocyte count and the serum bilirubin, on roentgen studies of the bones and on the failure to respond to iron medication. The remainder of the positive reactors, numbering 24, may be classified as belonging to the sickle cell trait group. None of these patients had anemia. With the exception of 1, they were in the hospital for disorders obviously unrelated to the sickling phenomenon. In regard to the exception, a girl aged 6 years with the signs of cerebral thrombosis of unknown origin, the etiologic possibility of the sickling tendency had to be seriously considered. Bauer[8] has emphasized the significance of such manifestations of sickle cell disease.

In only 1 case were the rapid test positive in result and the control entirely negative after forty-eight hours. In 1 out of the 38 cases—i. e. in 2.6 per cent—the rapid test was negative in result after five minutes but positive after fifteen minutes. In no case was the bacteriologic reaction negative and the control positive. The results of our investigations are summarized in tables 1 and 2.

1	0	3+										

* *An explanation of the grading scale may be found in table 1.*

As can be seen from the tables, the rapid test is so sensitive that no differentiation can be made in vitro between the erythrocytes of healthy persons harboring the sickle cell trait and the patients afflicted with sickle cell anemia. This is in accordance with the early observations of Hahn,[3b] who studied the sickle phenomenon with the gas chamber method. Both procedures create the most favorable conditions for the development of the sickling process by rapid reduction of the hemoglobin. Therefore, the variable degree of structural alteration of the red cells which may also contribute to the result is of negligible significance for the bacteriologic test but of far greater importance for the moist stasis test, in which the reduction of oxyhemoglobin takes place much more slowly. The moist stasis test may permit the differentiation between trait and

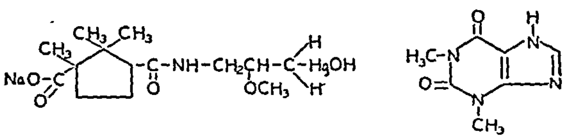

Fig. 3.—Mercurophylline.

All three mercurials have about the same degree of effectiveness. When they are given intravenously diuresis begins in about half an hour and reaches its peak within four hours. The amount of diuresis varies considerably from patient to patient and even in the same patient from time to time. However, if there is any edema fluid at all, one can anticipate some diuresis in well over 90 per cent of patients when the drug is given either intravenously or intramuscularly. When the patient has dehydration symptoms from rapid diuresis, it is probably better to give small doses of the diuretic more frequently rather than one large dose, such as 2 cc., once a week, for instance. Doses larger than 2 cc. should never be given. The intramuscular route is probably safer than the intravenous route.

A diuresis can be obtained in about 70 per cent of patients by the use of a suppository of either mersalyl and theophylline or "mercuzanthin." Rectal irritation may occur so that special care must be taken in the use of this dosage form.

The oral administration in the form of tablets is quite satisfactory in about 60 per cent of patients who have a moderate degree of congestive heart failure. A tablet may be given once or twice a day, preferably after a meal to avoid gastric irritation. Tablets of mersalyl and theophylline and of mercurophylline are available. In many cases by the judicious combination of the oral and parenteral dosage forms it is possible to give the injections much less frequently.

Morphine, meperidine hydrochloride and possibly other hypnotics or sedatives can exert an antidiuretic effect. It is important, then, if an adequate diuresis is not obtained with a mercurial diuretic to be sure that the patient is not receiving one of these drugs at the time.

Enhancement of mercurial diuresis can be produced by administration of ammonium chloride in doses of 3 Gm. a day. The diuresis may increase as much as 20 per cent if the ammonium chloride is administered for two or three days before the diuretic is given. Ammonium nitrate and potassium chloride will also enhance the diuresis but to a lesser extent. Urea in doses up to 60 Gm. per day is a diuretic acting as a nonthreshold substance, taking water with it when excreted by the kidney. It is frequently used as an adjuvant to mercurial diuresis.

Sodium dehydrocholate ("decholin sodium") will also enhance the effect of a mercurial diuretic. It can be given intravenously at the same time the diuretic is given.

The xanthines alone are rarely used today as diuretic agents except in those cases in which the patient is sensitive to all mercurial diuretics or otherwise when mercurial diuretics are contraindicated. Theobromine and sodium salicylate, theophylline, theophylline ethylenediamine and "theocalcin" are all of about equal effectiveness as diuretic agents. Diuresis, however, is not ly as complete or uniform as when the mercurials

The mercurial diuretics are not entirely free from danger, and care must be taken to observe danger signals while patients are receiving the treatment. Among the reactions which may be noted are: 1. Sensitization to one of the mercurials. This is manifested as urticaria, rash, chills and fever, sense of tightness in the chest, etc. If any signs of sensitization appear, one of the other mercurials should be substituted. All three diuretics have been reported as causing reactions in susceptible patients. 2. Digitalis toxicity. Spontaneous redigitalization even to the point of toxicity by mobilization of digitalis from edema fluid may occur. This may be avoided by giving the diuretic in smaller amounts or having the patient initially on a smaller digitalis maintenance dose. 3. Depletion of sodium. This may occur with muscle cramps, abdominal colic, nausea and vomiting, especially in patients on a low sodium diet. 4. Sudden death. This is relatively rare, considering the extensive use of these agents and the fact that they are used in many terminal cases. However, the incidence of sudden death can be reduced if care is taken not to give a diuretic that has caused a reaction previously and to avoid giving this medication to patients with advanced renal or hepatic disease.

ABSTRACT OF DISCUSSION

VALUE OF OXYGEN

Question: When can oxygen help patients with cardiac disease?

Answer: Oxygen is of value to any patient with cardiac disease who shows signs of arterial oxygen unsaturation. This is usually manifested by the presence of cyanosis. It should be pointed out, however, that cyanosis which is due to a shunt from the venous side to the arterial side, such as in congenital heart disease, or cyanosis related to definite stagnation of blood in the peripheral vessels is not helped by oxygen. Cyanosis in which there is arterial unsaturation due primarily to some disturbance in ventilation such as pulmonary congestion or pulmonary edema is definitely benefited by oxygen. Such conditions would occur in coronary artery thrombosis and in acute failure of the left ventricle.

AMMONIUM CHLORIDE AS DIURETIC

Question: How important is ammonium chloride as a diuretic per se?

Answer: Ammonium chloride alone is a mild diuretic. It serves an important purpose to substitute the ammonium radical for sodium. It is valuable as an adjuvant to a mercurial diuretic; the diuresis is increased by about 20 per cent when up to 3 Gm. of ammonium chloride is given per day.

SALICYLATES FOR RHEUMATIC FEVER

Question: Do the salicylates cure rheumatic fever?

Answer: Salicylates will relieve the articular symptoms of rheumatic fever, reduce the fever and make the patient much more comfortable. There is serious doubt, however, whether they influence in any way the course of the disease. Although salicylates have been given in large doses within recent years, the large doses are not free from danger. It should be emphasized that salicylate poisoning can occur and even death may result from an overdosage of salicylates.

UREA AS DIURETIC

Question: How effective is urea as a diuretic?

Answer: Urea as a diuretic has about the same effectiveness as ammonium chloride. It must be given in large doses.

COMPRESSION OF LIMBS AND VENESECTION

Question: What is the place of compression of the limbs and venesection in heart disease?

Answer: Rapid removal of blood from veins does relieve the load on the right side of the heart in acute heart failure. It is not generally a good plan to use this technic, particularly if the patient has anemia. As an emergency measure it has a limited value. It is possible by compression of the veins on all four extremities to pool a fairly large portion of the circulating blood in the extremities and thus relieve the load on the heart.

USE OF EPINEPHRINE IN CARDIAC ASTHMA

QUESTION: What is the value of epinephrine in cardiac asthma?

ANSWER: Cardiac asthma is another term for failure of the left ventricle of the heart and occurs in hypertensive heart disease, aortic insufficiency, aortic stenosis and, occasionally, coronary artery thrombosis. It is an indication of the inability of the left ventricle to pump out the blood that is received by it Epinephrine is not a particularly safe drug to use in such conditions because of the fact that it may cause a sudden rise in blood pressure. However, in small doses it does decrease the bronchial spasm which is associated with failure of the left ventricle and may give relief. It is probably better to give an intravenous injection of a rapidly acting glycoside such as ouabain and to administer oxygen by inhalation or to give aminophylline very slowly intravenously Attacks of cardiac asthma can be prevented by a maintenance dose of digitalis or by the use of mercurial diuretics.

DIGITALIS

HARRY GOLD*, M.D.
New York

The intensive search for purified glycosides of the digitalis series in the past seventy-five or eighty years has resulted in the discovery of numerous principles or mixtures of principles such as "digifolin," "digalen," "urginin," "digilanid," lanatoside C ("cedilanid"), digoxin, ouabain, strophanthin and digitoxin ("digitaline Nativelle"). The extent of absorption from the gastrointestinal tract constitutes the most important point of difference between these materials from the practical standpoint, and with respect to this point the vast majority of the purified materials offer no advantage over the whole digitalis leaf. Digitalis leaf has therefore continued to maintain its position of preeminence among the cardiac glycosides in common use. A satisfactory index of absorption in man may be obtained by the ratio of the oral to the intravenous dose necessary to produce the same effect in patients with auricular fibrillation. If this ratio is 10: 1, 10 per cent is absorbed; if the ratio is 5: 1, 20 per cent is absorbed, and if the ratio is 1: 1, 100 per cent is absorbed. For instance, in the case of a preparation of convallaria, 80 units by mouth were found to produce less effect than 3 units by vein; about 3 per cent was absorbed. An experiment showing the average behavior of 12 patients with auricular fibrillation who received 1.2 mg. of digitoxin, one time by mouth and at another time by vein, shows that in the case of this drug the ratio is 1: 1. This means that practically 100 per cent of an oral dose is absorbed. It was found that in order to produce the same effect in the same person, it requires 40 units of lanatoside C, 20 units of digitalis and only 4 units of digitoxin. Since digitoxin is all absorbed, it follows that only 20 per cent of the active material in digitalis is absorbed, and only 10 per cent of a dose of lanatoside C is absorbed. A comparison was made of digitalis and digitoxin. Patients with auricular fibrillation received 1.2 mg. of digitoxin at one time. The curve showing the development and the disappearance of the action was drawn. After the effects wore off, the same patients received 1.2 Gm. of digitalis at one time. The two curves are identical, showing that digitoxin acts like digitalis leaf when given by mouth, with respect to the speed of absorption and speed of elimination. The difference lies in their potency; digitoxin is approximately a thousand times as potent as the standard digitalis leaf of the present "Pharmacopoeia." Where one would use 1.2 Gm. of digitalis, one may obtain the same effect by using 1.2 mg. of digitoxin.

Because of the high potency of digitoxin, I have advocated the use of the average full digitalizing dose to be given at one time to patients with heart failure who have not recently had digitalis. This produces the full effects in six to ten hours, instead of the thirty-six to seventy-two hours as in the case of the divided dose method using digitalis leaf. Digitalis leaf cannot be used that way because the large quantity of nonabsorbable glycosides in the leaf cause vomiting by local action in 1 of every 5 patients.

Experience with this single digitalizing dose of digitoxin shows that 1.2 mg. given at one time may be expected to reduce the apex rate in patients with auricular fibrillation to between 60 and 85 a minute in about three fourths of the patients. This may be regarded as satisfactory digitalization. Some of the rest of the patients could do with somewhat less or require more to complete the digitalization.

The daily maintenance dose is usually 0.2 mg. In a few patients, the dose needs to be reduced to 0.1 mg., and some of the more tolerant patients require as high as 0.3 mg, or more daily.

The use of digitoxin has greatly simplified the problem of digitalization. I advocate it as the material of choice for routine oral digitalization and maintenance. There are reasons for the belief that it will not be long before the crude digitalis leaf or the tincture will be a cardiac medication of historical interest chiefly, and that digitoxin will take its place.

ABSTRACT OF DISCUSSION

VALUE OF AMINOPHYLLINE

QUESTION: Of what value is aminophylline (theophylline ethylenediamine) in coronary or other types of heart disease?

ANSWER: I do not believe that aminophylline has any value in the routine treatment of the angina of effort by oral administration. I know that it is widely used for that purpose, but in a study which we made some years ago by means of the "blind test" we found that patients were unable to distinguish aminophylline from sugar of milk tablets in relation to the control of cardiac pain on effort. There is no doubt that an intravenous injection of 0.24 Gm. of aminophylline will dilate the coronary vessels, and it may be of some use in acute coronary thrombosis. There are some who use it routinely after coronary thrombosis with a view to making patients less susceptible to ventricular fibrillation and reducing the size of the final scar. I do not use it that way. I am not impressed with the evidence that it produces those results. Furthermore, if I find it necessary to use a coronary vasodilator in coronary thrombosis, I give glyceryl trinitrate under the tongue at frequent intervals. It is more effective than aminophylline for that purpose. There is, of course, the problem of pulmonary edema with bronchospastic symptoms in coronary thrombosis, and in such cases an intravenous dose of aminophylline is often rather helpful. As a diuretic in congestive failure, which sometimes occurs in coronary artery disease, aminophylline is effective but not nearly so effective as the mercurial diuretics.

ALLERGY TO DIGITALIS

QUESTION: Is there any allergy to digitalis?

ANSWER: I have never seen any cases of allergy to digitalis. Several years ago a few cases of allergic reactions to digitali were reported. It must be rare if it occurs at all.

USE OF DIGITALIS TO PREVENT HEART FAILURE

QUESTION: Can digitalis be used to prevent heart f delay its onset or to check cardiac enlargement?

Read in a panel discussion on The Modern Management of Heart Disease in the General Scientific Meetings at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 9, 1947.

ANSWER: This question requires some dissection. There is no doubt that the maintenance dose of digitalis prevents the recurrence of heart failure, and theoretically its use before heart failure occurs might delay its onset or prevent failure. If one were to take a suggestion from this, one might begin the use of digitalis in a patient with cardiac disease long before failure is in evidence. It would mean keeping all patients with heart disease under the influence of digitalis for the rest of their life, for all patients with heart disease are candidates for failure. I do not pursue this practice. I am not certain whether I am right or wrong. I might mention that there is the view that cardiac enlargement is a manifestation of a failing muscle and that keeping the muscle under the influence of digitalis might retard enlargement. This is a point that cannot be easily proved.

EXPENSE OF DIGITALIS GLYCOSIDES

QUESTION: What is the expense of the digitalis glycosides in contrast to the dried leaf? Is such expense only a temporary drawback?

ANSWER: I do not know the relative costs of the various purified glycosides as compared with the ordinary dried leaf. In relation to digitoxin, which I believe should replace the crude leaf for routine oral administration, I was recently informed that the cost of the glycoside has been greatly reduced, and that a dose of digitoxin now costs the patients about the same as an equivalent dose of digitalis leaf.

NOTE BY DR. PAUL D. WHITE: In one of the large drugstores in Boston the following prices of digitalis preparations were quoted:

Trade Name	Source	Strength of Tablet	No. of Tablets	Retail Price at Pharmacy
Digitoxin	Abbott	0.20 mg	100	$1.85
Digitaline Nativelle	Fougera	0.20 mg.	100	3.00
Digitoxin	Squibb	0.20 mg.	100	1.85
Purodigin	Wyeth	0.20 mg.	100	1.65
Digoxin	Burroughs Wellcome	0.25 mg.	100	2.25
Cedilanid	Sandoz	0.50 mg.	100	4.00
Digilanid	Sandoz	0.50 mg.	100	3.00
Digiglusin	Lilly	0.1 Gm. (1½ gr.)	100	1.25
Digalen	Roche	0.1 Gm. (1½ gr.)	100	2.25
Dried leaf				
Digifoline	Ciba	0.1 Gm. (1½ gr.)	100	3.00
Digitalis	Davies, Rose	0.1 Gm. (1½ gr.)	100	2.20
Digitalis	Lederle	0.1 Gm. (1½ gr.)	100	1.07
Digifortis	Parke Davis	0.1 Gm. (1½ gr.)	100	2.15
Digitos	Sharp & Dohme	0.1 Gm. (1½ gr.)	100	1.25
Digitalis	Squibb	0.1 Gm. (1½ gr.)	100	1.25
Digitora	Upjohn	0.081 Gm. (1.28 gr.)	100	2.54

TOXICITY OF DIGITALIS LEAF

QUESTION: Is digitalis leaf more toxic than the glycosides when equally effective?

ANSWER. No. Whatever evidence there is on the subject shows that the spread between the therapeutic and toxic doses of digitoxin is the same as for digitalis leaf. It must be remembered, of course, that the potency of digitoxin is about 1,000 times that of digitalis and that one should prescribe 0.1 mg. of digitoxin where one would otherwise prescribe 0.1 Gm of digitalis.

The Circulatory System.—Arterial functions are controlled directly by peripheral centers, probably intramural. These are under a double dynamogenic influence: (a) that of the central nervous system (centers of the spinal cord and of the medulla); and (b) that of the cardiac sinus. This latter structure is able to induce either paralysis or tonic rigidity of the arteries, conditions which can be modified only by an extremely violent stimulation of the nerve centers as that which occurs with their destruction. The circulatory system has a complex regulatory mechanism which is influenced by the nervous system but has in itself the means of self-regulation.--Marceau, F.: Physiological Properties of Arteries, *Experimental Medicine and Surgery*, February, 1948.

QUINIDINE

LOUIS N. KATZ, M.D.
Chicago

There is a remarkable similarity in the discovery of the utility of quinidine with that of digitalis in that both were made by laymen. In 1914 one of Wenckebach's[1] patients informed him that the quinine which he had prescribed for malaria made his irregular heart action (due to auricular fibrillation) regular. Wenckebach was quick to find that quinine was an effective drug in the treatment of auricular fibrillation. Frey,[2] in 1918, established the fact that quinidine, a closely related compound, was more effective for this purpose. This was soon confirmed and extended by many workers, notably by Sir Thomas Lewis.[3] However, the early enthusiasm for quinidine soon waned because of a number of unexpected deaths attributed to it, and the pendulum swung back to nearly complete abandonment of the drug. Recently, as experience in its use improved, it has come to play an important role in cardiac therapy.

Its recent use has been increased in part because of the growing realization that large doses may be used with relative safety as well as because of the establishment of its effectiveness in ventricular tachycardia and in cases of coronary disease with premature systoles. Its utility in converting auricular fibrillation to sinus rhythm has long been established.

In this presentation a summary will be given of the present status of quinidine in cardiac therapy with some notes on the most recent developments.

It is now established[4] that quinidine prolongs the refractory period of the heart and the electrical systole of the ventricles. It prolongs conduction in the ventricles, in the auriculoventricular junction and, to a certain extent, in the auricles. It decreases the excitability of the myocardium and acts as a "soothing agent" on ectopic pacemakers. It depresses the sinus node and tends thereby to slow the heart rate. It paralyzes the action of the vagus nerve, which tends to neutralize to a certain extent its direct effects particularly on the sinus node and auricles. So far as it leads to a slowing of the heart rate it causes an increased amplitude of contraction, since more time is available for filling of the heart. In excess, however, it is a poison which tends to depress the myocardium and may lead to respiratory disturbances and even respiratory arrest. By virtue of its direct action on the smooth muscles of the blood vessels it may, with large doses, cause a fall in blood pressure. These multiple actions of quinidine explain the fact that contrary effects on certain properties of the heart may develop.

Quinidine has definite effects on the electrocardiogram.[5] It alters the P wave and the QRS complex.

From the Cardiovascular Department, Michael Reese Hospital. This department is supported in part by the Michael Reese Research Foundation.

[5] Katz, L. N.: Electrocardiography, ed. 2, Philadelphia, Lea & Febiger, 1946.

It prolongs QRS duration, leading to intraventricular block. It prolongs the P-R interval and may lead to more advanced auriculoventricular block. It may cause sinoauricular block. It leads to deviations of the S-T segment and may greatly alter the T wave, inverting it, notching it and prolonging its duration. It may lead to ectopic rhythms of various sorts. Particularly hazardous is the appearance, with excessive doses, of ventricular premature systoles, tachycardia and fibrillation.

Quinidine is rapidly absorbed and excreted. With the oral route, its maximum effect is obtained in two to four hours. This has been demonstrated indirectly by its effect on the auricular rate in auricular fibrillation, its effect on the duration of electrical systole and directly by chemical analysis of the blood.[6] With intramuscular or intravenous administration, the maximum effect occurs sooner, in one-half to one and one-half hours. With the oral route, minimal residual effects persist for six to eight hours, and the effect is completely gone and no further urinary excretion occurs in twelve to twenty-four hours. When repeated doses are given the effects of each are additive. The clinical implications from these data are: (1) that repeated oral doses given more than six hours apart are not cumulative; (2) that the interval between doses should be less than six hours and preferably two to four hours, and (3) that cumulation may occur when the drug is administered every hour or two.

One of the important considerations of quinidine is its toxicity.[7] This may be the result of idiosyncrasy with the symptoms of cinchonism. While this is rare, it is safest to employ a test dose of 0.2 Gm. by mouth and wait two to three hours for reaction before proceeding further. Cinchonism may also develop during therapy with larger doses of quinidine. The evidence of this intoxication includes tinnitus, vertigo, visual disturbances, nausea, vomiting, diarrhea, headache, confusion, syncope, fever, cutaneous rashes, petechiae and angioneurotic edema. More serious than these are the respiratory disturbances such as asthma, depression of breathing and even respiratory arrest. A troublesome finding in its use in auricular fibrillation or flutter is the paradoxic tachycardia which may follow the slowing of the auricular rate. For this reason some clinicians prefer to depress auriculoventricular conduction with digitalis in such cases before or simultaneously with quinidine. A serious hazard is the development of ventricular fibrillation or cardiac asystole. The danger of the occurrence of embolism when auricular fibrillation is converted to sinus rhythm must be considered. However careful studies show that this does not occur as often as suspected. Many of the episodes attributed to embolism are really because the direct effect on the heart leads to asystole or ventricular fibrillation. It is stated that the occurrence of petechiae is to be considered a warning sign of impending embolization.

INDICATIONS FOR USE OF QUINIDINE

The indications for the use of quinidine are at least seven in number:

1. Quinidine is an effective drug in breaking the mechanism of paroxysmal tachycardia of supraventricular origin. It has been widely employed for this purpose with excellent results.

2. Quinidine has been effectively employed to break the mechanism of paroxysmal ventricular tachycardia, chaotic heart action and, on occasion, even paroxysmal ventricular fibrillation. These mechanisms are so detrimental to the heart, especially when complicated by organic heart disease, that quinidine has been a blessing under such circumstances. Papaverine has been employed for similar purposes.[8]

3. Quinidine has been employed prophylactically to prevent recurrent paroxysmal arrhythmias. It has proved to be as valuable prophylactically as in breaking the mechanism of these forms of rapid heart action.

4. One of the newer developments in the use of quinidine is its employment to suppress frequent premature systoles. In normal subjects this should be employed only when the premature systoles cause distressing symptoms. For example, I have recommended its use by a surgeon who during operation experienced frequent premature systoles which were subjectively very disturbing whenever he ran into unexpected difficulties. It proved effective. There is no need to stress the fact that premature systoles without symptoms occurring in normal persons require no therapy, and care should be taken not to give cause for "cardiac fixation" in such subjects by suggestion of therapy. Quinidine may be used when digitalis causes premature systoles. Of course, under these circumstances digitalis should be stopped or the dose diminished. However, the use of quinidine will tend to lessen such digitalis-engendered premature systoles, especially when the benefits of digitalis require a dose which leads to ectopic beats. Quinidine may be used prophylactically in patients with mitral stenosis complicated by frequent auricular premature systoles in order to prevent or delay the onset of auricular fibrillation.

However, the most important use of quinidine in the case of premature systoles is the suppression of ventricular premature systoles in patients with coronary disease, whether this be an acute infarction or a variety of chronic coronary insufficiency. By "soothing" the ectopic pacemaker quinidine tends to avoid the risks of the development of paroxysmal tachycardia and the more serious ventricular fibrillation, which may cause unexpected death. In the presence of ventricular premature systoles in coronary disease quinidine is one of the important and potent forms of therapy. Some have gone so far as to employ quinidine in all cases of recent infarction. Quinidine will definitely lessen deaths in coronary disease attributed to ventricular fibrillation. In chronic coronary insufficiency it will lessen the frequency of congestive failure and angina pectoris, both of which may be precipitated by frequent premature systoles. Under these circumstances quinidine is one of the potent drugs available in prophylaxis of angina pectoris and heart failure.

5. Recently[9] it has been shown that quinidine in large doses will abolish, in most cases, the mechanism of the Wolff-Parkinson-White syndrome. This is used diagnostically and not therapeutically.

this may be followed by a shock state identical to that seen during the war, or following trauma or surgical procedure. At the Michael Reese Hospital, my colleague, Dr. William Brams, in an unpublished study has indicated that desoxyephedrine appears to be successful in overcoming the vascular collapse. If his results are substantiated by further experience a worth while addition to our armamentarium is at hand. When shock develops after a recent myocardial infarction one is dealing with a real emergency, since the chance that shock will lead to death is increased in the presence of the acute damage to the heart. In shock the circulating blood volume declines and hemoconcentration occurs. It is therefore obvious that the manner of counteracting it is to add fluid to the circulation, and plasma is the ideal fluid. The risk of overloading the heart by adding plasma to the circulation is exaggerated, provided the plasma infusion is not too rapidly administered. Within limits it is not the quantity of plasma given but the rate of administration that is disturbing. The work of Altchule has shown that even the failing heart can cope with infusions into the blood stream. In the presence of a recent myocardial infarction the plasma infusion must be carefully watched in the hospital, and during its administration the level of venous pressure and the clinical state of the patient followed. Whenever the venous pressure begins to rise rapidly and in an accelerated fashion the limit of the heart is reached and the plasma should be stopped or the rate of infusion sharply decreased. It should be stopped also if rales appear in the lungs. Of course, administration of the plasma can be stopped when definite improvement of the circulation is obtained or when it is obvious that the infusion is acting detrimentally. I do not want to be misunderstood as advocating the indiscriminate use of plasma, but I believe that plasma properly administered has a definite role in cardiogenic shock with low venous pressure just as it does in traumatic and surgical shock with hemoconcentration. Of course, the risks are greater in the patient with recent myocardial infarction since the damage to the heart is the initiating cause of the shock. Nevertheless this does not negate the use of plasma, and brilliant results have been reported. Plasma in recent myocardial infarction complicated by shock is heroic therapy.

RUTIN IN HYPERTENSION

Question: What is the value of rutin in hypertension?

Answer: The work of Griffith has been confirmed in showing that rutin tends to prevent hemorrhagic manifestations and counteracts capillary fragility. It, therefore, seems reasonable that it may be of value in counteracting hemorrhagic manifestations in hypertension. However, the final decision as to the utility of rutin must await a wider clinical experience.

HYPNOTICS AND SEDATIVES

Question: What is the place of hypnotics and sedatives in cardiac therapy?

Answer: Hypnotics and sedatives are of value in heart disease not only by virtue of their relieving or lessening apprehension and dyspnea but also by favoring sleep. It is so common an experience that it is almost redundant to restate it, that a good night's sleep has a remarkable effect on the physical state of the patient with cardiac disease and that contrariwise a poor night's sleep has a deleterious effect. In principle, the action of hypnotics and sedatives is to decrease the twenty-four hour work and energy requirements of the body which must of necessity lessen the requirements for hard work on the part of the heart. Since the heart must completely recover during the succeeding diastole for the work it does during its systole, it is obvious that any lessening of the work requirements will be beneficial. Imperfect sleep, restlessness and emotional upsets all put added strain on the heart. They should therefore be avoided as far as possible. Dyspnea also increases the energy requirements of the body and therefore serves as a strain on the heart. Sedation which lessens dyspnea and makes breathing more deliberate therefore reduces the strain on the heart. It must also be recalled that sedatives may lessen coughing, and a cough—it must be emphasized since it is not widely enough recognized—puts a great strain on the heart. Clinicians should be concerned about these matters as much as they are about the administration of drugs like digitalis, the mercurials and quinidine.

PAPAVERINE

Question: Of what value is papaverine in heart disease?

Answer: I still believe that papaverine has a definite place in the treatment of coronary heart disease. It is a sedative which is not habit forming. It is a "soothing agent" on ectopic pacemakers and it is one of the most powerful of the coronary vasodilators available. These statements are based on actual observation of animals and human beings. Its use intravenously should be limited to a few cases of recent myocardial infarction in which one is tempted to use morphine intravenously or in cases of recent myocardial infarction complicated by paroxysmal ventricular tachycardia. For the latter, quinidine may be used and may be more effective, but quinidine is a protoplasmic poison and when given intravenously may be hazardous. Papaverine may also be used profitably in recent pulmonary embolism. The precaution in giving papaverine intravenously is to use a slow administration over minutes, but the dose to be used should be from 1 to 1½ grains (60 to 100 mg.). There are unpleasant side effects in some instances, and there may be a profound drop in blood pressure. These are its hazards and contraindicate its use. Oral administration of papaverine may be used in recent myocardial infarction to dilate the coronary arteries, and especially when ventricular premature systoles are encountered. A large daily dosage is to be employed, 1½ grains three to four times a day. It should be stopped when any unpleasant side effects appear. Papaverine is quickly excreted and does not accumulate when given at the rate schedule suggested. It has a definite place in recent myocardial infarction, but is not universally applicable. The greatest benefit to be derived from papaverine is in chronic coronary disease complicated by angina pectoris and more especially when ventricular premature systoles are present. For the latter, however, quinidine may be preferred, although there is no reason why quinidine and papaverine may not be used simultaneously. Again, unpleasant side actions are contraindications to the use of papaverine. For chronic coronary heart disease the dose of papaverine should be begun at 1 grain three to four times a day and should be increased until the effect desired is obtained or side actions require stoppage. The aim should be to use the minimal amount per day which is effective. After a short trial, absence of any positive effect should lead to its discontinuance. Papaverine appears to have no effect on supraventricular ectopic rhythms and should therefore not be used for auricular premature systoles, supraventricular paroxysmal tachycardia, auricular fibrillation or auricular flutter. At the present time we are making a resurvey of the effectiveness of papaverine in chronic coronary insufficiency to see whether or not our early enthusiasm can be verified. We hope to be able to report on this survey within the next year.

PANEL DISCUSSION

On papers by DeGraff, Gold and Katz

Paul D. White, M.D., Boston, Moderator

Dr. White: It is of great importance to us all to have frequent appraisals of the value of therapeutic measures, both old and new, especially in the case of such a common and serious condition as that of disorders of cardiac function. We are fortunate to have assembled here at this centennial session of the American Medical Association several authorities on the subject. It is also a satisfaction to tell you of a most instructive exhibit on "Cardiac Drugs" prepared by one of the members of the panel, Dr. DeGraff, for the Cardiovascular Section of the Scientific Exhibit; you will find it on the main central part of the stage in the large hall of this building.

Dr. George W. Pickering, London, England: To round off this discussion perhaps I should refer to some principles in the treatment of heart disease which are not quite so new. The physician is rarely able to cure heart disease in his patients. In 9 cases out of 10 he is dealing with the management of a chronic disease, and it is important that he should look at his patient in this light. He should for instance remember that it is easy to make an invalid out of a patient with cardiac disease by inflicting unnecessary and petty restrictions and by arousing unnecessary alarm. We learnt a good deal about the importance of psychologic factors in heart disease during the recent war, when once again the problem of neurocirculatory asthenia became acute. Many of us have suspected that the doctor might play an important part in the causation of this malady. Paul Wood provided interesting figures in support of this view. In 33 of a series of 59 recruits who had been wrongly informed that they had heart disease neurocirculatory asthenia developed, and in 26 it did not. Of the 59, 30 had a family history of cardiac neurosis or nervousness, and in 27 of these neurocirculatory asthenia developed and in only 3 it did not. In 48 subjects activity was restricted by the doctor; of these 37 obeyed and 11 disobeyed; of 28 with a positive family history 27 obeyed and 1 disobeyed the doctor's instructions. In other words, in a patient with a family history of nervous breakdowns who obeys his doctor's instructions regarding restriction of activity de Costa's syndrome is extremely likely to develop, even when the patient has no organic heart disease. Some consider, and I am one of them, that the symptoms of neurocirculatory asthenia are no less likely to develop if the patient has in fact an organic cardiac lesion. It is therefore of the first importance in dealing with heart disease that the patient should not be frightened. With regard to treatment by drugs I confess that I am a medical anachronism and that I still use the powdered leaf of digitalis in the treatment of heart failure. This became almost obligatory in Great Britain during the war because of shortage of alcohol and manufacturing difficulties. I have been satisfied with the result, and have become so familiar with the use of the powdered leaf that I have not yet seen good reason to change. I am undoubtedly conservative, but I tell myself that it is more important for a general physician who has to deal with many kinds of maladies to be really familiar with one good preparation of a potent drug than to acquire the latest refinements.

Dr. Gold. I note that Dr. DeGraff still speaks of the use of the mercurial diuretics in heart failure when patients no longer respond to digitalis. This is the traditional way of viewing the utility of the mercurial diuretics. We no longer think this correct. The mercurial diuretics represent the most important addition to the list of cardiac medications, and they are indicated in every case of congestive failure. A great deal is lost in the efficiency of treatment if we wait to put them to use only after we have discovered that the patient does not respond sufficiently to rest and digitalis. We have just completed a study in which we found that if patients with congestive failure receive digitalis and the mercurial diuretic simultaneously and systematically, immeasurably better results may be expected; namely, complete disappearance of congestive failure, in 90 instead of approximately 50 per cent of cases, and a reduction in the period of hospitalization to about one third of the time that it takes to produce complete recovery from congestive failure by the prevailing methods in which the mercurial diuretic is put to use only after digitalis has failed to bring about satisfactory results.

Dr. DeGraff: I agree with Dr. Gold that mercurial diuretics are of utmost importance in the treatment of congestive heart failure and that the combined use of a mercurial diuretic and digitalis will relieve congestive heart failure more effectively than either one alone. However, the tendency to use mercurial diuretics alone at very short intervals in high doses not only may be dangerous but may cause the patient to suffer from severe symptoms of dehydration. Except in the later stages of their disease, most patients with heart disease can be kept free of failure by the oral use of a digitalis preparation, salt-poor diet and limitation of physical activity with occasional periods of bed rest. I do not see the necessity of giving such patients mercurial diuretics either intravenously or intramuscularly. As the heart disease progresses, a mercurial diuretic will be needed. One should at first try an oral preparation, and then if that is not sufficiently effective, the parenteral use of a mercurial diuretic is indicated. In his discussion of the cardiac glycosides, Dr. Gold has stressed the question of the completeness of absorption of digitoxin as compared with other glycosides. He failed to take into account that digitoxin has an exceedingly long latent period and a very long period of dissipation, factors which would definitely influence the experiments which he cites. As a matter of fact, whether the absorption from the gastrointestinal tract of the glycosides digitoxin, digoxin, lanatoside C and gitalin is or is not 100 per cent is not important, since extensive clinical studies by many observers have already amply demonstrated that all of these glycosides are sufficiently well and uniformly enough absorbed to be used when digitalis is indicated. In our experience, the extremely long latent period and the slow rate of dissipation of digitoxin make this glycoside less desirable for rapid oral digitalization or for maintenance than, for instance, digoxin. Should a patient become toxic from digitoxin, the symptoms may persist as long as a week, whereas toxicity is of much shorter duration with the other glycosides. Although Dr. Gold states that some patients could do with somewhat less or require more to complete the digitalization, he persists in advising a single initial dose of 1.2 mg. of digitoxin. If some patients could do with less, then why start with this dose? We find that a much safer starting dose is 0.6 to 0.8 mg., depending on the weight and age of the patient. For total digitalization with digitoxin Batterman and I have found that an average of 2.2 mg. is necessary, with the extremes of 0.8 mg. to 5.0 mg. The use of the cardiac glycosides represents an advance in treatment in that relatively pure principles are given rather than mixtures. It must be pointed out, however, that each glycoside has its own peculiarities. These are concerned not only with dosage, but with the time at which the effect begins after administration, the rate of dissipation, and the duration of toxicity.

Dr. Katz: I believe that digitalis should be given as pure glycosides in preference to whole leaf. Infusions and tinctures are going out of fashion. Our experience with digitoxin coincides with that of Dr. Gold. In addition to the slowly excreted digitoxin I would favor the use orally of some more rapidly excreted glycosides, such as digoxin and cedilanid. These latter may be used also intravenously for rapid action, but for quicker action strophanthin K or ouabain is preferable. I believe that by and large these glycosides operate in a similar fashion; their differences in action depend on the rate of their absorption and the rate of their excretion and destruction. I am sure that with time the English cardiologists will universally favor the use of pure glycosides. They are already using digoxin.

Dr. White: In the time that remains I shall make a few summary remarks concerning drugs in cardiac therapy. First, I want to emphasize that digitalis leaf itself in powdered form is still an effective drug in the treatment of congestive heart failure and in reducing the ventricular rate in auricular fibrillation and flutter. Its strength, of course, should be checked, but inasmuch as practically all the proprietary preparations of digitalis leaf on the market today are carefully standardized and reliable one may have much more confidence in the use of the crude digitalis leaf than was possible years ago, and, so far as I know, it still remains the least expensive way to give digitalis. As has been brought out in the discussion, the effect of digitalis is dependent on absorption, in large part at least, but there are individual variations and experience with each patient must determine the optimal dose for that patient. Certainly, as pointed out by Dr. Gold and others, digitoxin and others of the purified preparations are satisfactory now for routine use and have the advantage over the leaf itself that one may rely on the preparation quantitatively by weight without the need of standardization except on each individual patient. It would appear that we are going through a transitional period from the use of the pure digitalis leaf to the use of the pure glycosides. The transition certainly has been slow to date, however, for Nativelle as long as one hundred years ago produced the first purified glycoside (digitaline), which is our digitoxin of today. As for mercurial diuretics, one mu admit that they have been a very important addition to therapeutic armamentarium in the treatment of congestion of all sorts, particularly that due to heart failure, during the past two decades. However, they must be suited also to the individual patient and may on occasion produce toxic effects. One of these toxic effects is due to digitalis intoxication as the result of the transfer to the circulating blood of edema and serous cavity fluids containing digitalis which may have already been given in full dosage. In the use of mercurials the intravenous route is the best and the intramuscular route second best: less satisfactory is the rectal route, and least of all oral medication It is to be remembered that mercurial poisoning may be induced by oral therapy. Although the treatment of congestion by mercurials may be carried on for years successfully and be given even as often as every day because of the lack of accumulation, it is usually possible to reduce greatly the amount of mercurial diuretic needed or even to omit it altogether, with great benefit to the patient who may be fatigued by vigorous diuresis, if one reduces the sodium intake to a low level. During the last few years I have been able to dispense with mercurial diuretics altogether or to use them infrequently in many of my patients with myocardial failure.

I would like to add concerning the mercurial diuretics a word as to dosage. Two cubic centimeters are often too much, given either intramuscularly or intravenously, and I find that on occasion ½ cc. or even ¼ cc. intravenously has a good effect and is less exhausting. Such smaller doses may also be given more often without upsetting the patient. Ammonium chloride not only enhances mercurial diuresis but acts also by itself. It is more effective if not given constantly and it may be reserved for a few days at the time of the injection of a mercurial diuretic or it may be used three or four days at a time say every two weeks. The xanthine diuretics have been largely given up because of the greater effectiveness of mercury. As has been pointed out, morphine and Meperidine may decrease mercurial diuresis. Quinidine has come back into routine use in many places. In fact, we have never abandoned it at the Massachusetts General Hospital and I have found it helpful in many cases during the last twenty years. Its advantages far exceed its disadvantages such as its toxic effects and danger. Moreover, it should be used in prophylaxis as well as in treatment. I agree with Dr. Katz in supporting its use in coronary heart disease and have routinely given it every three to four hours in the dosage of 0.2 Gm. (3 grains) of the sulfate during the first two weeks after the onset of acute myocardial infarction. Fagarine I have not yet received from South America, although it was to have come for us to try last year. Aminophylline has its greatest value in improving respiratory function and in clearing, at least temporarily, Cheyne-Stokes breathing and cardiac asthma. It is not per se a heart stimulant. Glyceryl trinitrate I often use prophylactically in the small dosage of 1/200 of a grain (0.3 mg.) or less. Finally, I want to emphasize the value of other methods of treatment as touched on by Dr. Pickering, a proper balance between rest and activity, physical and mental, individual testing of reaction to tobacco, the importance of expert nursing, which may make the difference between success and failure, and the use of an optimistic outlook at the time of detailed explanation of their troubles to patients with cardiac disease who are usually intelligent and who, if told about their condition, are more likely to cooperate in their treatment themselves. We should constantly watch out for and seek sound new measures of treatment but also should hold on to the best measures of the past until something really better comes along. I would like to attend a panel like this after another hundred years. Perhaps there won't need to be any such panel if we can only learn about the underlying causes of heart disease and failure In conclusion, I thank the panel members for their remarks and yourselves for your attention.

Murmurs of Congenital Heart Disease.--The murmur of patent ductus arteriosus is a continuous one lasting throughout systole and diastole, with intensification in early diastole where it covers the second heart sound and proceeds to obscure the third heart sound as well.--Evans, W.: *British Heart Journal*, October, 1947.

SARCOIDOSIS

A Review and an Appraisal

HENRY E. MICHELSON, M.D.
Minneapolis

The purpose of this paper is to assemble, to evaluate and if possible to add to the known facts about the condition for which I prefer the term sarcoidosis. The disease has been recognized for about half a century, and although many observers and investigators have contributed their findings Boeck's name will remain most prominent in the minds of students of this interesting disease. Hutchinson, Besnier, Schaumann, Darier and Pautrier have all made contributions, and in more recent years Leitner[1] and Coste[2] have helped to clarify the diverse collection of biologic and clinical findings which constitute sarcoidosis and have collected in their writings the best of the investigations and discussions anent the etiology, morphology and course of this disease.

I believe that for the present the name sarcoidosis is preferable, because it implies a wider distribution than sarcoid and emphasizes systemic involvement. Furthermore, the employment of men's names would result in a long compound title. Hunter's[3] historical sketch covers the evolution of the nomenclature. Sarcoidosis, Besnier-Boeck-Schaumann's disease, benign lymphogranulomatosis, epithelioid reticuloendothelial granuloma, noncaseating tuberculosis and other names have been proposed, but until more definite etiologic evidence supplies a term which indicates the cause of the disease, sarcoidosis would seem to be the most concisely descriptive; "sarcoid" allows complete identification, while the ending "osis" implies something more than merely a cutaneous lesion.

The present conception of this disease is that it is systemic, following a chronic course and having the characteristics of a benign infection. Its prodromal and early stages are not well known, and in most patients the lesions regress and disappear. The locations of this disease are apparently manifold; the more thorough and refined investigations became, the more tissues were added to the long list of those where sarcoid inflammation has been located.

One of the challenges that the disease presents is the difficulty and danger of a purely clinical diagnosis. No examination of a patient in whom sarcoidosis is suspected is complete without searching for lesions on the skin and mucous membranes. The superficial nodes and palpable glands as well as the eyes and small bones of the extremities should be examined, and roentgenologic studies of the thorax, hands and feet are imperative. More refined procedures such as sternal biopsy, electrocardiographic study and examination of the blood are also indicated but are not so productive of valuable evidence. Positive diagnosis rests on histologic examination, and it is doubtful whether a diagnosis of sarcoidosis can be accepted without such microscopic evidence.

The immunobiologic state of the patient is evaluated by the tuberculin test and more recently by Kveim's

test. Because of the frequency of a negative reaction in this disease to various dilutions of tuberculin, a tremendous amount of effort has been expended in exploring the so-called positive anergy and its significance concerning a tuberculous etiology. Granting that a negative reaction cannot be overlooked, nevertheless it appears to have been overemphasized to the exclusion of a possibly more fruitful search for the presence or absence of a bacillary cause. Few investigations have been directed along bacteriologic lines other than searches for the tubercle bacillus.

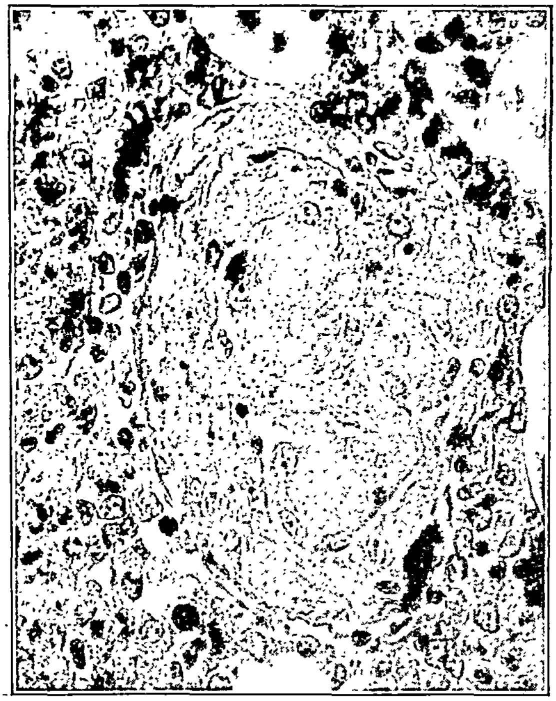
Sarcoidosis may occur at any age, having been found in infants and the aged, in both sexes and in all races; however, geographic location appears to have some importance. The Scandinavian writers have certainly led in the number of articles, but the great number of patients with sarcoidosis found in the polyglot population of the United States speaks against a racial preference. In the American Negro, however, sarcoidosis, or possibly a sarcoid-like tuberculosis, is a problem by itself, and for the time being I believe that discussion and deductions would be simplified if this group of patients were kept apart until more positive knowledge is acquired. Those whose investigations are confined to Negroes have the better opportunity to establish or deny the relationship of sarcoidosis to the development of frank tuberculosis. Whether it is a transition or a complication or whether the biologic elements control the course of events should be and undoubtedly will be proved by special investigations made on this group.

EVOLUTION

The prodromal and early manifestations of sarcoidosis are not known. What may dermatologists look for as a beginning sign or symptom in such patients? It may well be that we shall continue to find the first evidences in the skin because internal lesions, even though they precede cutaneous lesions, provoke no symptoms. Some sarcoidosis patients admit that a persistent erythematous patch has existed at the site of a subsequent node, but as a rule cutaneous lesions develop insiduously. Forssman[4] critically examined some cases of erythema nodosum and erythema multiforme, with negative tuberculin reactions, having early sarcoidosis in mind. In 3 of 10 cases, using Lemming's method of injections of BCG (Bacillus of Calmette and Gúerin) with subsequent histologic examination, he found pathologic reactions similar to those found in sarcoidosis. He wondered whether some cases of erythema nodosum or multiforme might not represent the acute stage of some disease, the lesions being merely a link in a chain of evidence which eventually would lead to a diagnosis. This is an attractive hypothesis and should be kept in mind when histories of patients with sarcoidosis are taken. The early cases as observed by Kyrle and Gans are well known by all students of this subject, but they bring up this query: Since the tuberculous etiology is by no means proved, are we justified in diagnosing a case as sarcoidosis, despite the histologic observations, if tubercle bacilli have been demonstrated, or are we then dealing with true tuberculosis? I would be inclined to believe the latter, and certainly so if the bacilli in addition to other unmistakable findings of tuberculosis were demonstrated.

CUTANEOUS LESIONS

It is not within the province of this paper to review again the various morphologic forms of cutaneous and subcutaneous lesions found in sarcoidosis. I do want to emphasize that almost every type of cutaneous change from erythema to formation of tumor has been attributed to this disease, by the histologic finding. I believe that we should stress the polymorphy, avoid the use of terms such as Boeck's miliary sarcoid, lupus pernio and Darier-Roussy sarcoid, and use descriptive terms such as papular cutaneous or nodular subcutaneous lesions, always retaining the diagnosis of sarcoidosis and listing the positive findings. For example: sarcoidosis with (*a*) papular cutaneous lesions; (*b*) pulmonary lesions; (*c*) enlarged inguinal nodes. One must keep in mind the decidedly atypical cutaneous lesions. I recall a patient whose lesions were indistinguishable from granuloma annulare and another whose lesions looked almost like acrodermatitis chronica atrophicans. To repeat, a microscopic examination is essential, and even then only sarcoid structure can be diagnosed, not sarcoidosis.



Sternal preparation showing granuloma consistent with diagnosis of sarcoid

Lesions in the mucous membrane are often described, but in my material not so often seen. The question of tonsillar biopsy offers the objection that in pulmonary tuberculosis *tuberculoid infiltrate may be found in the* tonsils. Involvement of the larynx and the upper respiratory tract is apparently rare in sarcoidosis as contrasted with tuberculosis.

Lymph nodes and glandular enlargements vary greatly in size and extent of involvement. In my material they are not striking, but in the reported cases the finding is frequent. The parotid, submaxillary and lachrimal glands are often reported enlarged and the syndrome of Heerfordt is of particular interest because of the rapid and at times febrile course.

Various internal glands have been invaded with symptoms provoked because of interference with a gland's particular function, as when the pituitary or thyroid gland has been involved.

The internal organs such as the heart, kidneys and spleen often take part in the process, but the contents of the thoracic cavity and the liver are most interesting because by means of x-ray or liver puncture one may obtain valuable evidence of the lungs and hilar glands. It need only be mentioned that here one may have lesions which are easily demonstrated and often present. Sarcoidosis involving the lungs can hardly be called a respiratory disease because as a rule it is symptomless, even though the lungs, pleura and hilar glands have extensive encroachment.

Van Buchem[5] performed liver punctures on 14 patients with sarcoidosis, results of whose hepatic function tests were normal. He found miliary sarcoid lesions in 11 of the specimens. Liver puncture offers another approach to the survey of the disease.

*Data on Patients with Proved Cases of Sarcoidosis**

Patient	Duration, Yr.	Age	Sex	Race	*Skin*	Nodes	Roentgenogram of Chest	Roentgenogram of *Bones*	Roentgenogram of *Bowel*	Tuberculin Reaction, *1:100*	Involvement of Ear, Nose or Throat	Brucella Skin Tests

* There was no evidence of involvement of the eyes in any patient; general bacteriologic data indicated no abnormality; Brucella cultures were either negative or not done (patients A. L., G. M. and R. C.); Brucella agglutinations were negative or not done (patients A. L., G. M. and R. C.), and the urine of all patients was normal, as were the electrocardiograms.

ETIOLOGY

There is at present a choice of only two causes of sarcoidosis, the one being that the condition is some type of tuberculosis; the other that the disease has its own etiology. Since the theory of the tuberculous causation seems to have the most adherents, how or where is one to find the facts that finally will give irrefutable proof that the tubercle bacillus is the only cause of sarcoidosis?

Bacteriologists have searched for the cause of this disease in all of their accepted ways, and still the percentage of positive findings is much too low to be convincing. Direct methods, cultures and animal inoculations have all been tried. Special staining methods raise the percentage of positive findings a little, but on the whole attempts to incriminate the tubercle bacillus by bacteriologic means have been disappointing. Koch said that the indisputable proof of a tuberculous causation was to find the bacillus in the diseased tissue. Too few such searches have been made, and the newer methods of direct examination of excised, well identified, sarcoid lesions should be utilized.

The interpretation of histologic examination leaves much to be desired. A diagnosis of sarcoid structure can be made by this means, but the criteria on which sarcoidosis can be differentiated from tuberculosis, leprosy, brucellosis, foreign body reaction and other conditions have not been established sufficiently so that changes in the section under examination can be said to be exclusively sarcoidosis. The case reported by German[6] well illustrates this. His patient sustained an injury to the head when he fell against a canyon wall. Subsequently a tumor formed which was found microscopically to be of sarcoid structure about incorporated crystals proved to be silica. Roulet and Albertini[7] both have seen granulomas in brucellosis which were tuberculoid and could not be distinguished from sarcoid.

Neither the type of cells, the arrangement, the presence or absence of necrosis, nor the discovery of special bodies such as Schaumann[8] has found in his explorations makes it possible for a pathologist to say, "This is sarcoidosis and cannot be anything else!" When a section from a questionable case is compared with one from a positive case, it is readily seen how wide the boundary lines may be. The so-called epithelioid or naked tubercle really is not a tubercle. Certainly the large massive sarcoid structure found in true sarcoidosis is not the tuberculoid structure found in lupus vulgaris, but on the other hand areas can be found in lupus vulgaris that cannot be distinguished from sarcoidosis. Therefore the microscopic diagnosis must not be made on finding areas of massed epithelioid cells but on a survey of the entire section, and I want to repeat that the finding of an isolated so-called epithelioid tubercle, although it often is found, especially in lymph nodes, is a deceiving premise on which a diagnosis may rest. Classic sarcoidosis tissue is readily identified, but if there are observations which cast doubt on the diagnosis, it is best not to go beyond a descriptive and inclusive diagnosis. Much has been written about the age of the lesion, and still biopsies made on the same patient over a period of years have shown a surprising stability of structure. On the other hand, when a lesion is in a regressive stage, then the histology is much altered. Therefore it is not the age, but the stage of the lesion, that is important. To reiterate, before one makes a diagnosis on sarcoid structure he should demand a clinical review and weigh the evidence before making a decision.

[7] Roulet and Albertini, in discussion on Zollinger and Meyenberg: Ueber eigenartige perivaskulare Granulomatose des Gehirns, Schweiz. med. Wchnschr. **72:** 826, 1942.

If histology were the only basis for alining sarcoidosis with some other known condition, then one could as readily decide that it was a form of leprosy as that it was a form of tuberculosis. As a matter of fact, leprosy produces a granuloma in the skin which resembles sarcoid more than any tuberculoderma does. Leprosy offers other analogous facts too. The slow onset, the various phases and the inability to find organisms in the tuberculoid variety are points in common; there are many arguments, however, against leprosy as a causative factor in sarcoidosis.

Since there are fairly accurate tests for brucellosis, Brucella melitensis may be eliminated as the cause of this condition. There are, however, a number of similarities between the two conditions, which somewhat strengthens the view that if the bacillus of brucellosis can produce so varied a syndrome as brucellosis, then a specific organism could readily provoke all the reactions that have been found in sarcoidosis.

If dermatologists, bacteriologists and pathologists cannot definitely decide about the tuberculous etiology of sarcoidosis, where may one expect to find help? I believe that it should come from the experts in tuberculosis. Can this array of findings which make up sarcoidosis be accepted as a type of tuberculosis? Does any known form of undisputed tuberculosis offer comparable findings? Mylius and Schürmann,[9] Pinner,[10] Hagn-Meincke[11] and others have compared sarcoidosis with noncaseating tuberculosis or with indolent tuberculosis, but patients with this condition have pulmonary tuberculosis which may and often does change in type and become one of the more serious forms of the disease. Furthermore, in patients with this chronic productive type of tuberculosis, even though there may occasionally be concomitant lesions, such as ocular or osseous lesions, they are not found with nearly the regularity that they are in patients with sarcoidosis; also the prognosis in patients with indolent tuberculosis rests largely on the course of events in the patient's life. Undue stress and strain, a concurrent infection or residence in an unfavorable climate may and often does bring about dire consequences, but patients with sarcoidosis do not seem to be so affected. If sarcoidosis is a form of tuberculosis, then the indolent form of tuberculosis so well described by Gloyne[12] best affords comparison; yet sarcoidosis is very different. Tuberculosis rarely if ever yields such extensive findings as does sarcoidosis. The tubercle bacillus seems to select its tissue and confine its ravages there. Patients with lupus vulgaris rarely have active glandular, osseous and pulmonary tuberculosis in addition to cutaneous lesions. Having a close association with Glen Lake Tuberculosis Sanatorium for a long period impressed me with the fact that patients with mixed tuberculosis are rare. The number of cases of pulmonary tuberculosis in which lesions of skin, bone or gland developed was comparatively small. A review of patients with sarcoidosis, on the other hand, reveals that almost all of them had disseminated lesions and that involvement of only one organ system was the exception. In this respect the two conditions are entirely different. Tuberculosis ignored progresses. An organized regimen, active treatment, awareness of the possibilities and cooperation are necessary to cure or check the disease. Sarcoidosis may be entirely ignored, and with few exceptions the patient does just as well, or better, than with medical intervention. There is an environmental and family factor in tuberculosis. Great stress is laid on finding the infecting source—the contact. Patients with sarcoidosis share their condition with no one in their immediate sphere. There are few contact cases. If the tubercle bacillus is the cause, can the patient with sarcoidosis render the bacillus noninfectious to others? It is hard for me to accept the tuberculosis theory of etiology.

The epidemiology and pathogenesis of tuberculosis have been the subject of a vast amount of research, and regardless of one's particular views certain well known facts have become established. For example, the changing clinical types, the effect of the times—the increase in tuberculosis in war-torn countries and the influence of organized control—but sarcoidosis goes serenely on in its own peculiar way.

Thanks to the work of Ghon and his pupils, the primary focus is accepted as the starting point of tuberculosis. Do patients with sarcoidosis have a primary lesion? If so, is it in the lung and if in the lung does it have the histology of sarcoid? Obviously these are difficult questions to answer. A number of years ago I wrote to Professor Ghon and asked whether they had ever encountered a primary focus which showed sarcoid structure. Dr. Rudolf Bezecny answered that they had not. This may not mean much, but if the patient with sarcoidosis has such unusual resistance to tubercle bacilli, is he born that way or does he acquire this reactional partial immunity? The power to suppress the tuberculin reaction must either be inherent or acquired if the cause of sarcoidosis is tuberculous. Surely the microbe does not explain this, for in cases in which the bacilli were found they have not been the attenuated types.

No amount of conjecture will solve this problem. It must be approached with well directed research.

Dermatologists, and I believe oculists, have been all too willing to diagnose a variety of conditions on a purely morphologic and histologic basis as being tuberculosis. I need only to mention with what alacrity dermatologists diagnose rosacea-like (micropapular) tuberculid with no confirmatory evidence of tuberculosis.

Since pathologic reactions have been provoked by various agents which result in microscopic findings that are indistinguishable from sarcoid, the view that sarcoidosis is not a specific disease, but rather a type of response, has been accepted by certain observers. That histologic evidence characteristic of sarcoid may be found in many conditions is true, but patients who have the disease called sarcoidosis have other confirmatory manifestations, and all such patients have so much in common that to me it appears that there must be a common etiologic agent.

Tuberculosis, leprosy and brucellosis occur in various forms, and still there is always enough evidence so that the disease is diagnosed as such. Syphilis also is protean in its manifestations, but for this disease there are specific remedies and one sees this great variety of lesions respond to a single drug with equal rapidity. Another proof of its entity.

The Kviem test if perfected will be of great diagnostic value. It should be of immense value in investigating sarcoidosis. Especially should it help in excluding tuberculosis, if that is possible, but researches should be directed toward discovering an etiologic agent.

In order to procure a base line co-workers and I decided to hospitalize patients with proved cases of sarcoidosis and study them with all the means at our command.

What do we learn, then, from these findings? 1. The history throws no light on the onset or prodromal signs of this disease. 2. The patients all were in reasonably good health, although in 1 case (Mrs. W.) there were periods of ill health and these periods were associated with the appearance of new lesions in previously uninvolved areas. 3. Roentgenologic examination of the thorax, feet and hands yielded evidence of the disease in some cases and in these instances was of definite value in diagnosis. 4. The histology of cutaneous lesions was diagnostic and hence the more characteristic the lesions were, the more indubitable was the microscopic diagnosis. 5. Examination of material obtained by sternal puncture was valuable and in 1 instance showed evidence of granuloma that was consistent with the other findings but alone would not have permitted making an unequivocable diagnosis of sarcoidosis. 6. Extensive studies (Drs. Wesley Spink, Wendall Hall, A. I. Braude) failed to reveal any connection between sarcoidosis and brucellosis in 8 classic cases of sarcoidosis.

CONCLUSIONS

1. Sarcoidosis is the best term at present to designate this condition. Sarcoidosis usually involves a number of different tissues and the patient should always be examined for extensive distribution. The disease is usually benign in its course and more or less self limited. No treatment known to date brings about rapid disappearance of the lesions. Vitamin D_2 therapy, although worthy of more extensive trial, has not been nearly as effective as in lupus vulgaris. The cause is not yet known and the explanation for the anergy often present in this condition is not clear. Microscopic study of excised lesions permits a diagnosis of sarcoid structure, but the diagnosis of sarcoidosis must be based on the sum total of the evidence obtained in each case.

ABSTRACT OF DISCUSSION

Dr. Fred D. Weidman, Philadelphia: As usual, Dr. Michelson's presentation has been most lucid. His paper is comprehensive and closely reasoned. On the perennial question of nomenclature, I would accept the substitute of "sarcoidosis," provided it were established that every case of what we are pleased to call sarcoid was a widely disseminated disease. I wonder if that is quite the case. I feel sure that the majority of cases of Boeck's sarcoid (what we call that) do not present demonstrable evidence of widespread dissemination. Time and time again in our society presentations, the report is that the bones were examined roentgenologically; the mediastinum did not show any hilar enlargement; the lymph nodes were not enlarged. In other words, it appears that the disease was not widely disseminated. I would prefer until that time has arrived to stick to sarcoid. After all, dermatologists have priority in the matter. Dermatologists used sarcoid before the internists used sarcoidosis. Of course, when the cause is discovered we may think differently. The second point is the matter of the analogous diseases which Dr. Michelson had to exclude. He mentioned brucellosis, and that is one of the highest points in his presentation. He has excluded that as the explanation of the sarcoid reaction. I would like to add one more, namely, leishmaniasis. I have seen a sarcoid type of reaction in leishmaniasis. As to the American Negro, I agree with him entirely. Dr. Klauder and I were careful when we reported a very early case of this disease to give it a different title from sarcoid. We called it "Multiple Sarcoid-like Granulomas of the Skin of Undetermined Nature" (Arch. Dermat. & Syph. **13:** 374-379 [May] 1926). Finally, the histology: What Dr. Michelson said about sarcoid holds good for a host of other dermatologic conditions. There are many expressions of change of other diseases in which a given picture in a given subject will not be diagnostic. That goes for syphilis, tuberculosis, many inflammatory and other dermatoses. In syphilis it is only occasionally that there are enough criteria whereby we can state that the dominant character favors a diagnosis of syphilis.

Dr. Arthur C. Curtis, Ann Arbor, Mich.: Ray and Shipman in 1923 showed that epithelioid cell tubercles could be produced with chloroform-soluble lipins of the tubercle bacilli. Defatted and chloroform-soluble lipins from grass and colon bacilli produced the same type of lesions; the former associated with many giant cells. Florence Sabin, while observing the cellular changes in the milk spots of the omentum of rabbits, saw monocytes and clasmatocytes pick up injected phosphatide and become transformed into epithelioid cells and Langhans giant cells. Her studies also showed that animals, given antigenic amounts of the phosphatide, would develop antibodies to it. With Smithburn, she later showed that when the typical cellular response to the phosphatide was produced—and she thinks the epithelioid cell reaction can be called the phosphatide phase of the disease—hypersensitiveness to tuberculin did not occur. This may have some bearing in the positive anergy reaction so often seen in sarcoidosis. W. M. German reported a case of sarcoid-like lesion appearing in an old scar fourteen years later, in a mountain climber who fell and injured his scalp. He excised the tumor. Pathologic examination of the lesion showed whorls and masses of epithelioid cells and giant cells of the foreign body type. In the latter, particles of silica were seen, and he postulated that silica was the causative factor. He suggested that perhaps silicosis could produce a foreign body reaction similar to sarcoid. The late Dr. Gardner at Saranac Lake continued this work and showed that the injection intravenously of silica dioxide produced lesions in liver, bone and lymph nodes indistinguishable from tuberculosis. When it was inhaled, similar lesions occurred in the lungs. J. T. Fallon, in Canada, who continued the work of Gardner, found exactly the same thing that has been described by Gardner and was impressed by the amount of phospholipid associated with lesions in the lungs produced by silica dioxide which had been inhaled by rabbits. The silica-free phosphatide was extracted from the lungs and then introduced into the lungs of fresh animals. The same epithelioid cell response occurred. From this work one might infer that the naked tubercule of epithelioid cells characteristic of sarcoid may have several etiologies, but that behind its production lies a fat compound of the phosphatide type. In the work reported by Drs. Grekin and Taylor and myself in the *Journal of Investigative Dermatology*, Sept. 1947, on the treatment of sarcoidosis with calciferol and dihydrotachysterol (Curtis, A. C.; Taylor, H. and Grekin, R. H.: Sarcoidosis: I. Results of Treatment with Varying amounts of Calciferol and Dihydrotachysterol, J. Invest. Dermat. 9:131, 1947) it is our belief that these agents operate, not through their effect on calcium, but because they have some effect on the phosphorus of the phosphatide, which we think is important in the development of sarcoid lesions.

Dr. Henry E. Michelson, Minneapolis: I think if Dr. Weidman wishes to retain the term "sarcoid" that it should apply only to a local lesion, but if one looks long enough and far enough, one is apt to find other lesions, and therefore I prefer the term "sarcoidosis." As to the experimental work that Dr. Curtis mentioned, one must remember that in such experiments one produces lesions, not the disease. Sarcoidosis as a widely spread disease is one thing and a local lesion produced experimentally is another. German's case, in which silicate was the irritant, was interesting but it only emphasized what Dr. Oppenheim and others have brought out before, that local irritants, insoluble and unabsorbable, may produce this type of reaction. In a recent issue of *Acta dermato-venereologica* a fungoid cause for sarcoidosis was proposed, and it is worthy of consideration. About vitamin D$_2$, one must remember that almost all good drugs may be poisons when used in high enough dosage. Since sarcoidosis is a comparatively benign disease, I would be loath to use toxic doses of vitamin D in an effort to make lesions disappear.

Innervation of the Carotid Sinus.—There are four nerves which contribute to the innervation of the sinus and adjacent carotid body, namely, the glossopharyngeal, vagus, cervical, sympathetic, and hypoglossal. The branch to the hypoglossal is inconstant and the part played by this nerve is probably not important. The other three nerves show considerable variation in their gross anatomic arrangements but great constancy in their connections to the carotid sinus and the intercarotid plexus. Embryologically the mesoderm of the third branchial arch artery and the ectoderm of the glossopharyngeal nerve possess an early juxtaposition in the region which is the anlage of the carotid body and carotid sinus; elements from the sympathetic and the vagus enter only at a comparatively late stage of development. From anatomic dissection it has been shown that a distinct and constant branch of the glossopharyngeal nerve connects with the sinus and intercarotid plexus. The importance of this nerve is supported by its striking constancy in all species of animal. Ray, S., and Stewart, J.: (Surgery,) March 1948.

Clinical Notes, Suggestions and New Instruments

RELIEF OF MORPHINE ADDICTION BY PREFRONTAL LOBOTOMY

T. H. MASON, M. D. and W. B. HAMBY, M. D.

Buffalo

Since the development of psychosurgery, initiated by Egas Moniz[1] in 1935 and later advanced by Freeman and Watts[2] in the United States, therapeutic results have been attained in mainly two fields of endeavor; one in psychiatry, the other directed toward the relief of intractable pain. This case report analyzes a heretofore unrecorded situation of an unusual type of chronic pain associated with the habitual use of tremendous quantities of morphine sulfate, being relieved by prefrontal lobotomy.

REPORT OF CASE

Mr. A. C., a draftsman aged 39 years, was admitted to the Buffalo General Hospital on June 16, 1947. Three years earlier he had sustained a laminectomy for spinal epidural abscess extending from the eighth to the twelfth dorsal vertebra. He survived with spastic paraplegia, a sensory level reaching approximately the nipple line and sphincter difficulty. Over the intervening three years he had been nursed efficiently by his wife. About six months after discharge from the Buffalo General Hospital he first began to complain of excruciating pain which he described as an unbearable "curling of the toes." Later there developed sensations such as "squeezing of the testicles, clawing of the perineum," and intense "burning in the rectum." These were controlled by hypodermic injections of morphine sulfate. Increment from time to time was necessary to alleviate his pain. Equally harassing was his fear of failure to receive medication, so that about half of each interval was spent in reminding his wife not to forget the injection. Finally he was receiving 42 grains (2.73 Gm.) of morphine sulfate daily.

Examination revealed a pleasant, young-appearing, 42 year old man who seemed comfortable and well adjusted to his situation. Patchy leukoderma was seen over the right lower jaw. There was full range of motion of the upper extremities, and motor power was good. Total areflexia was present below the eighth dorsal vertebra with flaccid paraplegia and bilateral foot drop. Anesthesia extended downward from the nipple line, above which was a 3 inch (7.6 cm.) band of hyperesthesia. The anal sphincter was atonic, and catheterization was required to empty the bladder.

He was made comfortable by the accustomed dose of morphine, 7 grains (0.45 Gm.) every four hours. Without this he complained bitterly of pain and became irritable and restless. No earnest attempt was made to withhold the opiate because of the fear of severe withdrawal symptoms. The bladder was controlled by tidal drainage and small trophic ulcers were given special attention. Because of the good results from prefrontal lobotomy for relief of intractable pain obtained by Poppen[3] and ourselves, this procedure seemed desirable here.

On the third hospital day a prefrontal lobotomy was performed through bilateral coronal parasagittal trephine openings. During the immediate postoperative period the patient twice was given morphine sulfate, 1½ grains (0.09 Gm.) and later two individual doses of ½ grain (0.03 Gm.) each, for restlessness. After thirty postoperative hours had passed, the patient seemed to be doing well, and morphine was withdrawn completely. He showed the usual immediate effects of lobotomy, such as apathy, unconcern, disorientation, tactlessness and loss of initiative. His appetite increased. The complaint of pain in the head was expressed occasionally, but this was fleeting and

did not seem to disturb him. Injections of morphine were forgotten. He toyed and fussed with whatever was within reach. He became progressively more rational and conversational. Memory was good though emotional affect was lost. The patient remained moderately overactive and was discharged on the eleventh postoperative day in good condition.

Five months have passed since the operation, and he requires no opiates. He is rather comfortable and about to begin a course of paraplegic rehabilitation, toward which he was refractory prior to operation.

COMMENT

Dual effects were attained in this case of cord stump pain associated with severe narcotic addiction. The unbearable sensations which had been referred to anesthetic zones no longer disturbed him. His crying need for opiate and hypodermic relief was forgotten; all anxiety, emotion, foresight and insight in relation to pain were lost. Amnesia for the surgical treatment was present, but this has been a frequent result of disruption of frontal association and projection pathways. A small amount of morphine was given immediately after the operation because of apprehension in regard to withdrawal symptoms. As the patient began to show a good recovery on the second postoperative day, it was decided to withhold morphine completely, undesirable effects being watched for.[4] Severe withdrawal symptoms such as diarrhea, loss of weight and persistent vomiting did not occur, nor did the more moderate abstinence effects, dilated pupils, anorexia and gooseflesh. On the first and third postoperative days intermittent tremors were present in the left shoulder and hand. These were brief and sporadic, and may have been associated with the removal of morphine. Restlessness and overactivity that were present have been seen both in the abstinence syndrome and after lobotomy, so they could not be dissociated. It is common for addicts from whom narcotics have been withheld to manifest ily fever, increased respiratory rate, insomnia, yawning, crimation and diaphoresis.[4] These were not experienced by e patient.

There has been considerable discussion as to whether the so-called withdrawal symptoms are organic or psychic in origin. Light and his co-workers[5] in 1929 seemed convinced that there was an organic basis for the syndrome so commonly found. Goodman and Gilman[6] stated that symptoms start within four to twelve hours after the last dose of morphine is omitted and reach their peak in ninety-six, and then decline. This period coincides with our patient's slight tremors in the left upper extremity and restlessness.

This evidence would suggest that withdrawal symptoms are largely within the psychic sphere. Lobotomy, which nullifies emotional tension, in this case removed the psychologic necessity for morphine, leaving only the organic component for analysis. The only objective organic effect was mild tremor.

Davis and Martin[7] have described recently a type of diffuse burning pain in spinal lesions which is not relieved by cordotomy. It is thought to be transmitted over autonomic pathways to enter the cord at various levels. Our patient's pain seems to fall within this category. It is now fairly well accepted that intractable pain may be relieved by severing the frontal association and projection pathways.[3] This has been done with good results in cases in which the patient had been accustomed to therapeutic doses of opiates for the relief of chronic, unbearable pain. By personal correspondence[8] and review of the medical literature, we have found no previous record of the cure of morphine addiction by prefrontal lobotomy. It is not implied that psychosurgery should be resorted to in uncomplicated cases of opiate addiction. When addiction is associated with possible organic cause for pain and cannot be broken by medical or psychiatric therapy, lobotomy may prove useful. The results here suggest that withdrawal symptoms are for the most part within the psychic sphere, although no general conclusions can be reached from a single case study.

SUMMARY

An unusual type of persistent pain and an associated severe morphine addiction in a paraplegic patient were relieved by prefrontal lobotomy. Prompt removal of the drug on the second postoperative day produced relatively no withdrawal symptoms. It is suggested that the latter group of symptoms are largely psychic.

ADDENDUM

Since this article was submitted for publication it has come to our attention that a case reported by J. L. Poppen in the *Lahey Clinic Bulletin* (4:205, 1946) had relief of morphine addiction and intractable facial pain.

Council on Physical Medicine

REPORT OF THE COUNCIL

The Council on Physical Medicine has authorized publication of the following article:

HOWARD A. CARTER, *Secretary.*

EXPERIMENTAL PRODUCTION OF CANCER OF THE SKIN BY ULTRAVIOLET RADIATION

Its Implications in the Use of Sunlamps

W. W. COBLENTZ, Ph.D.
Washington, D. C.

Some fifteen years ago when the Council on Physical Medicine first undertook the formulation of specifications for accepting so-called sunlamps, qualitative experimental data were available to indicate the possibility of producing cancer on the ears of mice by excessive, often repeated doses of ultraviolet radiation. It was also known qualitatively that relatively small doses of ultraviolet radiation of wavelengths shorter than 2,800 angstrom units produce keratitis and conjunctivitis.

The sunlamps which were then on the market ranged from nondescript products to hot quartz mercury arc lamps, which are suitable only for professional use. Hence, after consultation with recognized authorities regarding the potential hazard of initiating cancer of the skin and the unquestionable hazard of causing conjunctivitis, and also with the Food and Drug Administration on what constitutes misbranding, standards for the acceptance of sunlamps[1] were promulgated.

In recent times quantitative data have been published on the spectral quality and total intensity of ultraviolet radiation required to produce erythema, keratitis, cancer of the skin and the like. The energy relations involved in these physiologic reactions form an interesting study, the results of which I now summarize.

Erythema.—A minimum perceptible erythema is defined as a reddening of the skin that disappears in fifteen to twenty hours after irradiation.

The erythema test now in common use is a quick, safe method of determining skin tolerance, which is especially important before irradiating large areas of a (blond) nontanning skin.

The spectral range of ultraviolet wavelengths in sunlight that produce erythema extends from about 2,900 to about 3,200 angstroms. To qualify as a sunlamp an artificial source must emit a specified minimum amount of ultraviolet radiation in this wave band.[1] This correlation was worked out about fifteen years ago by irradiating untanned persons with skin of average pigmentation.[2]

---

[1] Acceptance of Sunlamps, J. A. M. A. **102**: 42 (Jan. 6) 1934; **114**: 325 (Jan. 27) 1940; **118**: 298 (Jan. 24) 1942; revised. 1947.

To produce a minimum perceptible erythema on exposure to midsummer, noon hour sunlight, at sea level, requires from 1 to 2 million ergs/sq. cm.,[3] depending on the dryness of the skin.

The ultraviolet energy required to produce a minimum perceptible erythema, using sunlamps of types S 1 and R S, averages about 1,100,000 ergs/sq. cm.

In my tests of several makes of type R S sunlamps an exposure of three times the minimum perceptible erythema dose did not produce burns, but it left a tan that remained for one to two months.

As described elsewhere,[4] in sunlamps of types S 1 and R S the biologically effective radiation is emitted mostly in the intense emission lines of the high vapor pressure mercury arc, of wavelengths 2,967, 3,024 and 3,134 angstroms; and while the spectral energy distribution throughout the whole spectrum (ultraviolet, visible, infrared) is not closely similar to that of solar radiation, the same biologic effects are obtained. This is because the discrete emission lines happen to occur in the proper wavelengths and intensities to produce the same biologic effect as the more continuous but less intense spectrum of ultraviolet radiation that is integrated over the wave band extending from about 2,900 to 3,200 angstroms in sunlight at sea level.

Cancer of the Skin.—In determining the band of wavelengths specific in producing cell changes that lead to cancer on the ears of white mice Rusch, Kline and Baumann [5] used low vapor pressure cold quartz lamps (radiation of wavelength 2,537 angstroms) and high vapor pressure hot quartz mercury arc lamps, in which the filtered, "midultraviolet" radiation consisted principally of wavelengths 2,967, 3,024 and 3,132 angstroms, that occur in spectral quality but not necessarily in relative spectral intensity in types S 1 and R S sunlamps.

Data are given on the results of a daily carcinogenic dose of 35.7 million ergs/sq. cm. of "ultraviolet energy" (wavelengths 2,000 to 4,000 angstroms). This was equivalent to 6 to 8 million ergs/sq. cm. of "midultraviolet" radiation, or six to eight times the minimum perceptible erythema dose tolerated on the human skin, and equivalent to a second or third degree erythema when exposed to a type S 1 or R S sunlamp. Certainly such a dose could not be repeated day after day on the human skin.

They reported that, using carcinogenic amounts of radiant energy, well defined erythema occurred early in the experiments but subsided somewhat after three or four weeks. In some instances the ears of the white mice became ragged or stubby, but that did not seem to affect the incidence of cancer.

After continuing the exposures for one hundred and thirty-five days 44 per cent of the mice in group I (24 mice in a group) and 55 per cent of those in group II had tumors.

The results pertinent to the present discussion are that the "midultraviolet" energy (essentially of wavelengths 2,967, 3,024 and 3,132 angstroms) necessary to produce carcinogenesis in 50 per cent of the group of mice ranged from 672 to 2,360 million ergs/sq. cm. over the irradiation period of one hundred and thirty-five days, with a mean value of 1,598 million ergs/sq. cm. The incidence of tumors ultimately reached 70 per cent after one hundred and seventy days of irradiation.

The daily exposures to cold quartz mercury arc radiation (principally of wavelength 2,537 angstroms) for a much longer period and a much larger total dosage (5,712 million ergs/sq. cm.) produced no tumors. In contrast, as will be noted presently, a momentary exposure to only a small fraction of this amount of radiation from a cold quartz lamp is sufficient to cause conjunctivitis and keratitis.

By using these enormous doses of ultraviolet radiation, frequently applied, it was possible to show which particular band of wavelengths is specific in initiating cell changes that lead to cancer. In this respect it is an extremely important contribution to science.

The concomitant physiologic and photochemical reactions that are produced on much smaller doses of ultraviolet radiation of these same wavelengths will now be summarized.

Ultraviolet Radiation Therapy in Human Rickets.—An important use of a sunlamp is in a children's playroom, for the prevention of rickets. When the type S 1 sunlamp was first introduced, Gerstenberger and Russell [6] studied its efficiency as an antirachitic factor. For this purpose 2 (3 at the start) rachitic patients were exposed once a week, front and back, to a type S 1 sunlamp for a sufficient time to produce a definite erythema. Two of the infants were Negro and 1 was Italian. In other words, the skin was pigmented and presumably tolerated a greater dosage than could be given to a blond skin.

None of these patients showed progressive healing at the beginning of the treatment by ultraviolet radiation. Two weeks after treatment was begun (after two irradiations) the roentgenograms showed the beginning of healing, which was complete in five weeks in the infant with moderate rickets and in seven weeks in the (white) infant having severe rickets.

In other words, of the 2 patients for whom complete records were obtained, 1 had received five and the other seven irradiations that produced a definite erythema, which, according to the description of the authors, was an exposure of about two and one-half times as long as that required to produce a minimum perceptible erythema now commonly used as a maximum exposure.

From this I deduce that the single dose was about 2 to 2.5 million ergs/sq. cm., or a total of 10 to 12.5 million ergs/sq. cm. in the five treatments of the infant having moderate rickets and a total of 14 to 17.5 million ergs/sq. cm. during the seven irradiations of the infant having severe rickets.

In contrast, as previously described, using filtered radiation from a hot quartz mercury arc lamp, of wavelengths 2,894, 2,967, 3,024 and 3,132 angstroms, the total ultraviolet energy used in producing tumors on the ears of 50 per cent of a group of white mice was roughly one hundred and fifty to two hundred times the energy used in curing rickets in children with ultraviolet radiation from a type S 1 sunlamp emitting the same wavelengths and having, presumably, closely the same relative spectral intensities as used in the carcinogenic experiments.

Subsequent investigations by Gerstenberger and Horesh[7] and by Knudson[8] show that such heavy doses of ultraviolet radiation are not necessary, especially to prevent rickets. Moreover, infrequent irradiation seems to permit regeneration of injured tissue, if any injury occurs.

Pathologic Effects of Ultraviolet Radiation on the Eye.—In their investigations of the effect of ultraviolet on the eye Verhoeff and Bell[9] used heterogeneous radiation from a hot quartz and a magnetite arc lamp. Exposures were made on the eyes of rabbits and monkeys and on one human eye.

They found that the liminal exposure capable of producing photophthalmia to the extent of conjunctivitis accompanied by stippling of the cornea, in terms of ultraviolet radiation of wavelengths shorter than about 3,050 angstroms (determined by a filter method), was approximately 2 million ergs/sq. cm. If a factor is applied to include the recently determined[10] spectral keratitic response to an equal energy stimulus, their value is reduced to less than 1 million ergs/sq. cm.

In recent times, in connection with an investigation of injury to the eye from ultraviolet radiation in arc welding (using 300 to 400 amperes) Kinsey, Cogan and Drinker[11] found that the energy necessary to produce keratitis in man by ultraviolet radiation is approximately two thirds that required in rabbits.

On exposure of human beings at a distance of 7 feet (213.36 cm.) from a 300 ampere arc they found that ocular lesions were produced in thirty seconds. From their intensity measurements, made with a tantalum photocell calibrated against a cold quartz mercury arc lamp, I deduce that the ultraviolet energy (heterogeneous iron arc radiation of wavelengths shorter than 3,000 angstroms) required to produce keratitis was about 45,000 ergs/sq. cm. of equivalent 2,537 angstrom radiation. This value seems extremely low. It is important to note, however, that the uncomfortable gritty sensation caused by stippling of the cornea and by conjunctivitis is felt after much shorter exposures and lower intensities than those used in the herein described experiments on the eyes of animals. This I know from numerous personal experiences extending over a period of more than three decades, when ultraviolet radiation from a hot quartz mercury arc lamp was sometimes accidentally flashed back of my spectacles, causing a mild conjunctivitis on the outer corner of the eye.

An important paper by Cogan and Kinsey[10] gives the spectral keratitic reaction which requires the least energy (150,000 ergs/sq. cm.) using homogeneous radiation of wavelength 2,880 angstroms, in comparison with 180,000 ergs/sq. cm. to produce a minimum perceptible erythema with a wavelength of 2,967 angstroms.[2]

Using homogeneous radiation of wavelength 2,520 angstroms, 600,000 ergs/sq. cm. was required to produce a threshold keratitic reaction, in comparison with about 365,000 ergs/sq. cm., in summer and 750,000 ergs/sq. cm. in winter[2] to produce a minimum perceptible erythema with radiation from a cold quartz lamp emitting the same wavelength, 2,537 angstroms.

In practice the erythema produced by this amount of radiation of wavelength 2,537 angstroms is so evanescent (observable for only a short time, some three hours after irradiation) that easily twice that amount of radiation is applied to get a definite (minimum perceptible erythema; one that lasts ten to fifteen hours) reddening of the skin of average pigmentation, with no ill effects. On the other hand, photophthalmia is a painful experience with no factor of safety from injury, on overexposure.

These data show that practically the same amount of energy of wavelength 2,537 angstroms causes photophthalmia as is required to produce a minimum perceptible erythema on untanned skin. Hence, in irradiating the body with the cold quartz mercury arc lamp, unless eye-protective glasses are worn there is no factor of safety between a dose giving minimum perceptible erythema and photophthalmia consisting of conjunctivitis accompanied by stippling of the cornea.

Other objectionable features (such as deactivation of ergosterol) in using ultraviolet radiation of wavelengths shorter than about 2,800 angstroms in the home without the supervision of an experienced technician are summarized elsewhere.[12]

In a recent paper entitled "Ultraviolet Action Spectra," presented at the Chicago meeting (May 18 to 22, 1947) of the Federated Societies of Experimental Biology, Bachem[13] criticizes the Council on Physical Medicine for accepting sunlamps for home use without medical supervision, his objection being that they contain a "spectral range which permits easy burning and blistering and may produce skin cancer."

In his opinion "the proper spectrum for home lamps should contain the 2,600 and 3,600 angstrom areas without the 3,000 angstrom range." He does not consider the hazard of causing keratitis and conjunctivitis by radiation of wavelengths shorter than 2,800 angstroms a problem that (beginning with Louis Bell[9]) has claimed my attention for more than three decades in connection with the protection of industrial workers in electric welding and the like.

The only practical source that is available to emit the short ultraviolet wavelengths suggested by Bachem[13] is the low vapor pressure cold quartz mercury arc lamp with a strong emission line at 2,537 angstroms, which, as is well known, constitutes about 98 per cent of the total biologically effective radiation of 3,132 angstroms and shorter wavelength.[14]

To use ultraviolet radiation of these short wavelengths in so-called "home lamps" because they do not initiate cell changes that may perhaps produce cancer is impracticable because of the danger of causing photophthalmia. This is a certainty as just noted, unless glasses are worn, which is not enforceable in the home. On the other hand, from the foregoing analysis of the data on the excessive doses of ultraviolet used to incite cancer of the skin, that hazard seems potential.

[14] Such lamps, in quartz, generate an objectionable amount of ozone.

It is not my desire to belittle the fact that ultraviolet radiation of wavelengths 2,900 to 3,200 angstroms can be an inciting agent, an irritant, when too frequently applied to the skin in excessive doses. I agree with Blum[15] that, while it is unwise to apply to man these findings of cancer of the skin produced on laboratory animals, it is also unwise to minimize the possibility that cancer of the human skin may result from excessive ultraviolet irradiation.

However, ultraviolet lamps and so-called sunlamps have been in indiscriminate use for over two decades; and if there is a latent period in the development of cancer of the skin, no published reports seem to be forthcoming to indicate that irradiation with such lamps, long ago, was the initial cause. Now that more is known about dosage this potential hazard should become less, as it no doubt will with the increasing indifference to high pressure sales promotion of sunlamps and the waning fad of excessive sun bathing.

Council on Foods and Nutrition

This paper, prepared at the request of the Council on Foods and Nutrition, is one of a series which will appear in THE JOURNAL. The entire series will appear later in book form as the Council's Handbook of Nutrition.

FOODS OF PLANT ORIGIN

LEONARD A. MAYNARD, Ph.D.
and
WALTER L. NELSON, Ph.D.
Ithaca, N. Y.

Over 50 per cent of the American diet consists of foods of plant origin. Indirectly as foods for animals, plant products make an additional contribution to the human diet through their influence on the nutritive value of animal products.

In discussing nutritive values, it is necessary to make use of certain average figures for nutrient composition. Foods of plant origin are subject to rather wide variations in composition as influenced by genetic, soil and climatic factors. It is beyond the scope of this article to consider these factors. Their importance is illustrated by the reports of a number of investigators.[1] Some of the factors influencing mineral composition have been reviewed by Beeson.[2] Fortunately the consumer seldom gets his supply of a given food from a single agricultural source, and thus the significance of the wide variation in the composition of crops differently produced is not nearly so great as the individual values might suggest. There are also variations in foods as consumed caused by processing, storage and cooking factors. In the present article attention is called to these factors if they have a particular bearing on the significance of the average values cited. For convenience of discussion, the foods of plant origin are grouped as follows: cereals; legumes and nuts, potatoes, other root crops, tomatoes, leafy vegetables, miscellaneous vegetables, fruits, sugar, syrups and molasses and vegetable oils.

CEREALS

Under cereals are included the cereal grains and their products, including flour, bread, breakfast foods, crackers, cookies, pastry and macaroni. Because of the low cost of cereals in relation to most other foods, their consumption is largest among the low income groups. The importance of these foods in the diet has been set forth editorially in THE JOURNAL[3] as follows:

> The cereal grains are the backbone of the nutrition of most of the races of the earth. They are, as a rule, the cheapest sources of food fuel; so that corn, wheat, rice, rye, barley and oat kernels are to be found constituting a third or often much more of the calory intake of the millions of persons involved.

Cereals also provide a third or more of the protein of the American diet. While this protein is not so high in biologic value as that of animal products, combinations of cereal and animal protein provide a diet of excellent protein quality. Important amounts of phosphorus, iron, copper and other minerals and of certain vitamins are supplied by cereals. Generalizations here are of limited value, however, because of the differences among cereals and the losses which result from milling.

Wheat.—Wheat is by far the leading cereal in the diet in the United States, furnishing approximately 25 per cent of the total calories consumed. The total per capita consumption of flour for 1945 is estimated at 164 pounds (74 Kg.), 97 per cent of which was the milled product, leaving less than 5 pounds (2 Kg.) as whole wheat or graham flour. The consumption of wheat breakfast foods approximated 1½ pounds (0.7 Kg.) per capita. The proximate composition of the flours, as listed by Chatfield and Adams,[4] is presented in table 1.

TABLE 1.—*Proximate Composition of Whole Wheat and of White Flour*

	Protein, Percentage	Fat, Percentage	Carbohydrates, Percentage	Crude Fiber, Percentage
Wheat flour, graham.....	13.6	2.0	72.4	1.8
Wheat flour, patent.......	10.8	0.9	75.9	0.3

It is clear that wheat makes a substantial contribution to the protein needs of the diet. Using the percentage figure for patent flour, one may calculate that the average daily consumption of 6.8 ounces (225 Gm.) of flour supplies 22 Gm. of protein daily, or nearly one third the daily allowance. Whole wheat contains more protein than white flour, and its protein has a higher biologic value, but when white flour is supplemented with milk, eggs or meat a protein mixture of high biologic value results. The much lower fiber content of patent flour reflects the removal of the bran in milling. While bran contributes laxative qualities to the diet, it is poorly digested and may be somewhat irritating to the mucous membranes of the digestive tract. The physiologic effects of bran have been reviewed by the Council on Foods and Nutrition.[5]

Several reports[6] have indicated that the calcium, phosphorus and iron of whole wheat flour are poorly utilized and therefore the higher concentration of these nutritents in the whole wheat flours are for the most part an apparent and not a real benefit.

In table 2 are presented the vitamin and mineral values of whole wheat and white flour and, for comparative purposes, the enrichment levels of white patent flour. These levels are based on recommendations of the National Research Council and were compulsory under War Food Order No. 1 of the Federal Security Administration until Oct. 25, 1946. At present (1947) these levels are required by legislation in nineteen states and Puerto Rico and Hawaii. The values for thiamine, riboflavin, nicotinic acid and iron are taken from Tables of Food Composition.[7] Those for pantothenic acid and pyridoxine were supplied by Elvehjem.[8]

The large milling losses of vitamins and minerals are evident from this table. The data show that the outstanding superiority of enriched flour over ordinary white flour lies in its sixfold increase in thiamine content, the figure being 75 per cent of that for whole wheat flour. The data show that milling results in a 60 per cent loss of pantothenic acid and a 50 per cent loss of pyridoxine. Much of the phosphorus and certain other minerals are also lost.

The enriched flour now on the market is nearly all produced by adding the nutrients in question to the refined product. A somewhat similar product can be achieved by "longer extraction" in milling, that is, by retaining some of the vitamin and mineral rich portions of the wheat which are milled out in making patent flour. This is the procedure officially adopted in Canada, as described by Newman.[9]

Wheat flour is consumed to a large extent in the form of bread, of which 85 per cent is commercially baked. Most of this bread is made from white flour, but it is estimated that a majority of the bread now consumed is the enriched product. This enriched bread is obtained either by the use of enriched flour or by the direct addition of the specified minerals and vitamins to the dough.

An important factor in the nutritive value of bread is the extent to which nonfat dry milk solids are used in its manufacture. Six per cent of these is frequently mentioned as the desirable amount in modern bread, but apparently much bread is made with 3 per cent or even less when the cost of nonfat dry milk solids is high. Whole wheat bread is commonly made without milk solids. The inclusion of 6 per cent of the solids increases the calcium content of white bread four times and the phosphorus content twice and adds 0.06 mg. of thiamine and 0.36 mg. of riboflavin per pound. It also improves the protein value considerably. Several reports[10] have appeared showing the improvement in the protein value of white bread made with milk solids when 3 to 5 per cent of soybean flour or 1 to 3 per cent of a cultured food yeast replaced a corresponding amount of the wheat flour used in baking.

The proposed minimum standards for enriched bread which are now being followed are, per pound: thiamine 1.1 mg., riboflavin 0.7 mg., nicotinic acid 10 mg. and iron 8 mg. A similar content of nonfat dry milk solids being assumed, the thiamine content is approximately three times as large as that of ordinary bread, the iron content is increased four times and the nicotinic acid content three times. In other nutrients the enriched product falls somewhat short of whole wheat bread.

TABLE 2.—*Vitamin and Mineral Content of Flours*

	Whole Wheat Flour, Mg./Lb.	White Flour, Mg./Lb.	Enriched Flour,* Mg./Lb.
Thiamine	2.53	0.30	2.0
Riboflavin	0.56	0.15	1.2
Nicotinic acid	25.30	3.50	16.0
Iron	17.3	3.0	13.0
Pantothenic acid	6.03	2.50	
Pyridoxine	2.09	0.90	

* Minimum enrichment levels.

Since whole wheat bread contains the bran which is largely absent in white or in enriched bread, the question of relative digestibility is an important one. This question was thoroughly studied by Rubner[11] during World War I. He found that the advantage of the higher protein content of the unmilled product was offset by its lower digestibility and that it contained slightly less total available calories. Noteworthy modern studies have been published by Murlin and his associates.[12] The first study shows that whole wheat bread has in general a lower protein digestibility value but a higher protein biologic value. The second study reveals no significant differences in the digestibility of the carbohydrates of the two breads. The authors point out that any differences in protein or in available energy values are small and of little importance as compared with differences in vitamins and minerals.

Corn.—Corn meal is the chief form in which corn is used as human food, representing a per capita consumption of 23.4 pounds (11 Kg.) in 1939. An additional 8 pounds (4 Kg.) is consumed as breakfast foods, grits, hominy and canned corn.

The corn grain is approximately equal to the wheat grain in thiamine content but contains only one fourth as much nicotinic acid. It is a good source of phosphorus and iron and certain other minerals. But much of the corn meal and flour consumed, as well as the hominy, grits and breakfast foods, is in the form of milled products. The milling process removes the germ and the bran and thus takes out most of the

thiamine and minerals present in the entire kernel. The Food and Drug Administration,[13] however, has set standards for enriched corn meal and grits entering interstate commerce which require that each pound contain not less than 2.0 mg. and not more than 3.0 mg. of thiamine, not less than 1.2 mg. and not more than 1.8 mg. of riboflavin, not less than 16 mg. and not more than 24 mg. of nicotinic acid or nicotinamide, and not less than 13 and not more than 26 mg. of iron. North Carolina, South Carolina, Georgia, Alabama and Mississippi have compulsory legislation (1947) which requires that all degermed corn meal and grits sold in the state meet these requirements. These products contain 8 to 9 per cent of protein, which ranks below wheat in biologic value but which combines with milk to provide a protein mixture of high quality. Elvehjem[14] has recently reviewed the role of corn in pellagra-producing diets. The special reason for enriching corn with nicotinic acid is based on the fact that this cereal is used by certain groups in diets which, as a whole, are low in protein and specifically the amino acid tryptophane. Nicotinic acid can serve to decrease the requirement for tryptophane. Inasmuch as corn is low in both tryptophane and nicotinic acid, it is evident that more nicotinic acid is required. Yellow corn meal differs from the white variety, as well as from other cereals, in containing a significant amount of vitamin A: 350 to 500 international units per hundred grams. In view of the rather large consumption of corn meal and other milled corn products by certain groups of the population, the wider use of the unmilled or enriched meal or the development of milling methods which would retain nutrients now lost would be highly desirable.

Canned corn is equal to corn meal in energy and protein on an equivalent moisture basis and is superior to the milled product in mineral and thiamine content.

Oats.—Among the breakfast food cereals, oatmeal and rolled oats, the principal forms in which oats are consumed, rank first both in quantity eaten and in nutritive value. Approximately 529 million pounds (240 million Kg.) are consumed annually. In the milling of oats, only the fibrous hull and the adhering portions are removed, the germ and the other vitamin-rich and mineral-rich portions being left with the product used for human food. Thus oatmeal ranks nutritionally as a whole grain cereal rather than as a milled product.

Oat cereals rank above wheat products both in fuel value and in protein content. Their higher fuel value is due primarily to their fat content (7.4 per cent). Their protein content, over 14 per cent, outranks that of white wheat flour in biologic value. Both oatmeal and rolled oats are low in crude fiber and when properly cooked are highly digestible.

Oatmeal is considerably richer than whole wheat in thiamine. Aughey and Daniel[15] reported that one hundred and twenty minutes' cooking in a double boiler did not cause any appreciable loss of thiamine from rolled oats. The following values for the various vitamins have been reported[7] for uncooked oatmeal: thiamine 2.5 mg. per pound, riboflavin 0.63 mg. per pound and nicotinic acid 5.0 mg. per pound.

Oatmeal is a rich source of iron (23.4 mg. per pound). Its phosphorus content, 66 per cent of which is in the form of phytin, is similar to that of whole wheat.

Rice.—Rice supplies slightly more than 1 per cent of the calories of the average American diet, the annual per capita consumption being approximately 5 pounds (2 Kg.). White, or milled, rice, the form in which most of the consumption occurs, is essentially an energy food. The protein content is around 7.5 per cent, thus being lower than that of corn. Over 50 per cent of the minerals and 85 per cent of the thiamine of the entire kernel are lost in milling. In contrast, brown rice, the product that results when only the hull is removed, contains 0.7 to 0.9 mg. of thiamine per hundred grams. It is nutritionally superior in other respects also. A change from white to lightly milled rice would certainly be in the interests of better nutrition.

Recent developments in the nutritional improvement of white rice have been described by Kik and Williams.[16] Several processes have been proposed for the preparation of milled rice with improved retention of the various vitamins. A comparison of white rice prepared by the conversion process with that of raw rice is given in table 3. It can be seen that a high percentage of the vitamins are retained in the milled product when the conversion process is used.

TABLE 3.—*Thiamine, Riboflavin and Nicotinic Acid Content of Rice*

Type of Rice	Thiamine, Mg./Lb.	Riboflavin, Mg./Lb.	Nicotinic Acid, Mg./Lb.
Rough (brown)	1.48	0.28	26.6
Converted (milled)	1.36	0.20	20.7
Raw (milled)	0.20	0.08	8.3

Rye.—The consumption of rye, mostly as milled rye flour in bread, is less than 3 pounds (1.3 Kg.) per capita annually. This flour is similar to white wheat flour in energy and in protein content. The whole grain contains approximately 2.1 mg. of thiamine per pound, 0.95 mg. of riboflavin and 7.7 mg. of nicotinic acid. Although some of the vitamins are lost when rye flour is degerminated and bleached it is still a better source of most of the B complex factors than white wheat flour.

Barley.—A small amount of barley is consumed as pearl barley and as barley flour for infant feeding. These are milled products which are apparently similar to white wheat flour in energy value but lower in protein content. Milling removes minerals and vitamins to an extent similar to that in the case of wheat.

LEGUMES AND NUTS

Dry legume seeds, such as beans, peas and lentils, are approximately twice as rich in protein as the cereals. While most legume proteins are of rather low biologic value when fed alone, their deficiencies are made up by other proteins in a mixed diet. Dried beans, either home cooked or canned, are noteworthy as a cheap source of protein even though the digestibility is somewhat less than for protein from many other sources.

Dried navy and kidney beans, green or dried lima beans, green or dried peas, lentils and cow peas are all rich sources of thiamine, containing around 0.5 mg. per hundred grams of the dried seed. A part of this thiamine is lost, however, in the cooking process. Two thirds of a cup of baked, canned beans should nevertheless supply one eighth of the day's thiamine requirement. These legumes also supply significant amounts of riboflavin. Fresh green lima beans and peas are rich in ascorbic acid, but a large loss is involved in cooking. The legume seeds are noteworthy also for their iron content, the dried products containing from 6 to 10 mg. per hundred grams. Two thirds of a cup of baked beans will supply one half the daily adult allowance. Legume seeds are notably higher in calcium and in phosphorus than are even the whole cereal seeds.

---

[13] Enriched Corn Meal and Grits, Food and Drug Administration, Federal Register, May 7, 1947, p. 3112

[14] Elvehjem, C. A.: Corn and Pellagra, in Conference on Corn Enrichment, Clemson, S. C., Clemson Agricultural College, July 1947.

[15] Aughey, E., and Daniel, E. P.: Effect of Cooking on the Thiamine Content of Foods, J. Nutrition **19:** 285 (March) 1940.

[16] Kik, M. C., and Williams, R. R.: The Nutritional Improvement of White Rice, Bulletin 112, National Research Council, June 1945.

It is evident that a larger consumption of dried legumes, particularly in place of refined cereals, would improve the diet in several respects. Their cheapness commends them especially for use in low cost diets.

Green and yellow string and wax beans, classed as seed pods, are comparable to the legume seeds in protein, minerals and thiamine per unit of dry matter and in addition contain notable amounts of vitamin A, riboflavin and ascorbic acid.

Peanuts have nutritive values similar to those of the other legumes. They have a much higher energy value due to the high fat content (44 per cent), and the protein is of high biologic value. Peanut butter has a nutritive value similar to that of peanuts. Soybeans are nutritionally similar to peanuts. They are little used as human food in this country. Walnuts are comparable to peanuts in thiamine content, but almonds have somewhat less. All have a high fat and a high protein content and are comparable as sources of calcium and phosphorus.

VEGETABLES

Under the heading "vegetables" are grouped a great variety of foods which differ widely in their nutritive values.

Potatoes.—According to statistics of the United States Department of Agriculture, approximately 275,000,000 bushels of white or Irish potatoes are consumed in the United States per year, or approximately 125 pounds (57 Kg.) per capita. Thus, potatoes provide approximately 4 per cent of the total calory needs on the average. For many persons, however, particularly the lower income groups, potatoes make up a much larger part of the diet than this average figure indicates, and their nutritive value is of added concern accordingly.

Potatoes are primarily an energy food, consisting largely of starch. Approximately 10 per cent of the total calories are in the form of protein of good biologic value. The potato is low in fiber, and according to various investigators it is highly digestible (92 to 99 per cent). It is a significant source of iron, in that one medium-sized potato may provide as much as one tenth of the daily requirement.

As harvested, potatoes contain 12 to 35 mg. of ascorbic acid per hundred grams and thus provide a substantial amount of this vitamin. There is a continuous loss in storage, however, which amounts to 50 to 70 per cent in twelve months. The initial loss is rapid. There is a further loss in cooking, ranging from 14 to 66 per cent according to the procedure, as reported by Esselen and co-workers.[17]

The thiamine content of the potato ranges from 95 to 165 micrograms per hundred grams, which would mean from 8 to 14 per cent of the adult daily requirement in a 150 Gm. serving (approximately the average daily consumption) if it were not for cooking losses. The potato does not supply a significant amount of riboflavin. Iron is richest in the outer portions of the potato; vitamin C seems to be evenly distributed throughout. There is evidence that the vitamin and mineral loss is less in potatoes boiled with the skins on than when baked, but the loss is greatest for peeled potatoes.

The consumption of sweet potatoes in pounds is only about 25 per cent that of the white variety previously discussed. However, per unit weight it contributes appreciably more calories, owing to the higher dry matter content of the sweet variety. Like the white, the sweet potato is primarily an energy food, low in fiber and highly digestible. Only 6 per cent of the total calories are in the form of protein, as compared with 10 per cent for the white variety.

Sweet potatoes are especially noteworthy, however, for their vitamin A value (7,700 international units per hundred grams[7]). Thus, an average-sized serving would supply more than the adult daily allowance of 5,000 international units.[18] Sweet potatoes are apparently similar to white in vitamin C content but lower in thiamine. They are also lower in iron and make no significant contribution to the diet as regards other minerals, except possibly in certain trace elements. An excellent study of the nutritive value of dehydrated sweet potatoes has been published by Lease and Mitchell.[19]

Other Root Crops.—Among other root crops the carrot is high in carotene content. Converting the carotene into international units of vitamin A the values range from 2,200 to 10,000 units per hundred grams, so that approximately three fourths of a cup of cooked carrots should furnish one half to more than two times the daily adult allowance. However, there is some question as to how carotene from various sources is utilized by the body. Utilization values as low as 1 to 19 per cent for man have been reported in the literature.

Compared with the carrot on a calory basis, turnips furnish similar amounts of thiamine, riboflavin, iron and protein, 50 per cent more calcium and eight times as much vitamin C. Swede juice has been reported one half as rich as orange juice. One half a cup of properly cooked turnips should supply approximately one fifth the adult daily allowance of ascorbic acid. Beets are similar to carrots as regards riboflavin and vitamin C content and contain more iron and protein. Raw onions are also a good source of vitamin C,[7] but storage losses range from 14 to 50 per cent, and thus old onions are not a reliable source.

Tomatoes.—Tomatoes are important both because of their special nutritive values and because of their widespread production. They rank third in quantity among the vegetable crops, being exceeded only by white and sweet potatoes. Among the canned vegetables, the tomato in its various forms ranks first.

Tomatoes are outstanding as a source of ascorbic acid, having an average content of 25 mg. per hundred grams for the summer grown products. Thus one small tomato will supply about one third the recommended daily allowance for the adult (75 mg.). The acidity of the tomato protects it against any considerable loss in cooking. In the canning of tomatoes and tomato juice there is little loss of the vitamin if the process is properly carried out. However, tomato juice purchased on the retail market has been shown to vary considerably in ascorbic acid content. Values ranging from 2.5 mg. to 25.2 mg. per hundred grams have been reported. One 5 ounce (150 cc.) glass of tomato juice supplies about one third the daily allowance. Recent evidence indicates that tomatoes as purchased on the northern markets in winter contain much less ascorbic acid than those available in summer.

---

[17] Esselen, W. B.; Lyons, M. E., and Fellers, C. A.: The Composition and Nutritive Value of Potatoes, with Special Emphasis on Vitamin C, Bulletin 390, Massachusetts Agricultural Experimental Station, March 1942.

[18] In setting up this allowance, it was recognized that *somewhat more* would be required if all the units were furnished as carotene *and somewhat less* if all were furnished by vitamin A itself, *because* a unit in the *form of carotene* may be, under certain conditions at least, only about half as effective in human nutrition as a unit of vitamin A itself. *Thus,* the rating here given for sweet potatoes, while accurate for *comparison* with other plant sources of vitamin A, overrates the vegetable in *comparison* with a source of vitamin A *itself.* *The same* considerations apply to later *discussions of the* vitamin A value of the foods included in this paper.

[19] Lease, E. J., and Mitchell, J. H.: Biochemical and Nutritional Studies of Dehydrated Sweet Potato, Bulletin 329, *South Carolina Agricultural* Experiment Station, *June 1940.*

Tomatoes are also rich in carotene. Ripe tomatoes, fresh or canned, contain approximately 1,000 international units of vitamin A per hundred grams. This means that one small tomato or a 5 ounce glass of canned juice will supply about one fifth the daily adult allowance.

On the basis of the available figures, tomatoes in the amounts consumed cannot be considered as an important source of any of the B group of vitamins or of the mineral elements with the possible exception of iron.

Leafy Vegetables.—The leafy vegetables, including cabbage, kale, chard, broccoli, spinach, turnip greens, collards, lettuce and beet greens, are outstanding sources of certain minerals and vitamins. They are particularly noteworthy for their calcium, the important element in which cereals, potatoes and most other foods except milk and cheese are deficient. Among the leafy vegetables mentioned, turnip greens rank at the top in calcium content. One half cup (3 ounces, or 90 cc.) of the cooked greens will supply approximately one third the daily adult allowance. Broccoli, collards, kale, loose leaf lettuce and mustard greens are also rich sources. Head lettuce and cabbage are relatively low, but cabbage greens and the outer leaves of cabbage rank even higher than turnip greens.

Experiments by Fincke[20] have shown that the calcium content of broccoli and that of cauliflower are nearly as available as that of milk. Speirs[21] has reported that the utilization of calcium from turnip greens is about equal to that from milk but that the calcium in tender greens, collards and kale is less well utilized. The calcium of spinach, beet greens, chard and lamb's-quarters is not nutritionally available because of the high oxalic content of these vegetables.

The calcium contribution of green leafy vegetables becomes particularly important in diets containing little milk or cheese.

The green leafy vegetables are important sources of iron. A serving (3 ounces) of cooked turnip greens, mustard greens, spinach, chard or beet greens will supply approximately 25 per cent of the adult daily allowance. Kale supplies somewhat less and headed lettuce and cabbage are relatively poor sources.

The green leafy vegetables are all rich sources of carotene and thus make an important contribution to the vitamin A content of the diet. A range of 2,800 to 13,650 international units per hundred grams for kale, chard, spinach, turnip greens, dandelion greens and mustard greens has been reported.[7] The greener and leafier the product, the higher is the vitamin A content. Carotene from green leafy vegetables seems to be better utilized than that from the yellow vegetables. Allowing for losses in cooking and for the fact that the vitamin allowance must be higher when carotene is the source, a 3 ounce serving of one of these greens can be relied on approximately to meet the day's needs. Headed cabbage and lettuce are relatively poor sources.

In the fresh state, the leafy vegetables are excellent sources of vitamin C. A cup of raw shredded cabbage will furnish nearly a third of the day's allowance. Watercress, collards, broccoli, turnip greens, mustard greens and kale are similar in vitamin C content to cabbage; beet greens and dandelion greens contain somewhat less; lettuce, escarole and endive contain much less. Leafy vegetables lose vitamin C by oxidation in storage and also in cooking. Further losses occur by solution in cooking if the cooking water is discarded. Gould, Tressler and King[22] found that, in cooking, 25 per cent of the vitamin C of cabbage was destroyed by oxidation and another 25 per cent lost in the cooking water. Other vegetables have shown similar losses. In the preparation of vegetables, further destruction of vitamin C by oxidation occurs when they are crushed or bruised or allowed to stand for long periods of time at room temperature both before and after cooking. Cutting and chopping into small pieces also accelerates the oxidation of vitamin C but in order to reduce the cooking time it is sometimes advisable to do this with large vegetables, particularly if they are cooked in very small amounts of water. Vitamin C losses can be decreased by refrigerating the vegetables until ready to prepare and serve. In cooking use as little water as possible, have the water boiling to start with, bring the water back to the boil quickly after adding the vegetables and keep the cooking time at a minimum. The same methods which help to conserve the vitamin C value will also conserve riboflavin, thiamine and mineral values. All these food components are more or less soluble in water.

Most of the green leafy vegetables are excellent sources of riboflavin, the leaves being much richer than the stems. A serving of cooked beet greens will supply about one fourth of the daily adult allowance. Spinach and kale supply about one fifth. Other greens supply a lesser amount, headed cabbage and lettuce ranking at the bottom of the list. Leafy vegetables are not a good source of thiamine, furnishing only 3 to 15 per cent of the adult daily allowance. The destruction in cooking usually does not exceed 10 to 15 per cent, and when large amounts of water are used and discarded, large additional losses occur by solution. Certain leafy vegetables have been found effective in preventing and curing pellagra. The following values have been reported for some of the green vegetables (mg. per hundred grams): spinach 0.70, broccoli 0.90, cress 1.0 to 2.0 and kale 2.0.

In the amounts commonly consumed, leafy vegetables are of little significance as energy foods, but their higher carbohydrate content provides roughage, which is needed in certain diets. They are relatively richer in protein than in calories, and their protein ranks above seed proteins in general in biologic value. However, the actual contribution to the diet in the amounts commonly consumed is small.

Miscellaneous Vegetables.—There are several other vegetables which, although limited as to general use, make important contributions to the diet of certain groups. The Hubbard, or winter, variety of yellow squash contains 5,000 international units of vitamin A per hundred grams. One half cup of the cooked product supplies nearly one half the adult daily allowance. Summer squash contains much less. Pumpkin furnishes approximately one fourth as much as winter squash.

[20] Fincke, M. L.: The Utilization of the Calcium of Cauliflower and Broccoli, J. Nutrition **22**: 477 (Nov.) 1941.

[21] Speirs, M.: The Utilization of Calcium in Various Greens, J. Nutrition **17**: 557 (June) 1939.

[22] Gould, S.; Tressler, D. K., and King, C. G.: Vitamin C Content of Vegetables: V. Cabbage, Food Research **1**: 427 (Sept.-Oct.) 1936.

A serving of fresh asparagus (nonbleached) can furnish approximately one seventh the day's allowance of vitamin A and one sixth that of vitamin C. It is also a significant source of calcium and iron. Brussel sprouts are rich sources of vitamin C and also furnish significant amounts of iron, calcium and vitamin A. Cauliflower is notable for its content of ascorbic acid, thiamine and riboflavin.

One medium-sized sweet pepper will furnish 630 international units of vitamin A and 180 to 200 mg. of vitamin C. Chili peppers, whether fresh or dried, are a good source of vitamin A. Fresh chili is an excellent source of vitamin C. Some of the vitamin C is retained on canning. Okra contains 740 international units of vitamin A per hundred grams. Parsley, which is used mainly for decoration, is an excellent source of both vitamin A and iron. When fresh it furnishes some vitamin C.

FRUITS

According to United States Department of Agriculture statistics, the approximate per capita consumption of fruits, calculated on the fresh basis, is about 150 pounds (68 Kg.). Of this total, 75 per cent is consumed fresh and 15 per cent canned, and the remainder is divided between dried fruits and juices. Apples outranked all other fruits, representing over one fourth the total consumption. But citrus fruits as a class exceed apples by 50 per cent or more. The nutritive values of various fruits have been excellently summarized in an article by Morgan,[23] and we have drawn on this article for many of the data which follow.

Fruits do not contribute important amounts of either calories or proteins to the diet, but they are of outstanding value because of their content of certain vitamins and minerals. As a class, fruits are important sources of ascorbic acid, certain members of the B complex, vitamin A, iron and other minerals, but there is a large variation among the different kinds as regards the extent of their contributions.

The citrus fruits are especially important for their ascorbic acid content. A medium-sized orange weighing about 5½ ounces (155 Gm.) will meet the daily adult allowance. A somewhat greater weight of grapefruit is required. Four and one-half ounces (130 Gm.) of canned orange or lemon juice or 6 ounces (170 Gm.) of canned grapefruit juice would supply the daily allowance. While the citrus fruits cannot be considered important sources of other nutrients, they do contain iron, calcium and thiamine in amounts which are of some significance in the diet. Pineapples, which are consumed mostly canned or as juice, contain about half as much vitamin C as do citrus fruits and are in general similar in other values.

Apricots and yellow peaches are important sources of vitamin A. The day's adult allowance is supplied by 3½ ounces (100 Gm.) of fresh or canned apricots or by approximately three times as much fresh or canned peaches. Weight for weight, dried peaches and dried apricots supply approximately three times as much vitamin A as the fresh products. Cantaloupes contain about half as much of this vitamin as do fresh peaches, and they are an important source of ascorbic acid, being about equal to the citrus fruits. Dried prunes furnish significant amounts of vitamin A, riboflavin and thiamine. Plums rank above other fresh fruits in thiamine content. Apricots, peaches and to a lesser extent prunes are significant sources of iron.

Apples cannot be considered a large source of any vitamin or mineral nutrient. In view of their large consumption, however, they do make a significant contribution of ascorbic acid to the diet. A medium-sized apple weighing 6 ounces supplies on the average about one tenth the day's allowance, but there are decided differences among varieties. The keeping qualities of apples make it possible for them to be marketed throughout the winter in latitudes where fresh grown sources of vitamins are unavailable or high in price. In rural areas in which they are produced, home-stored apples undoubtedly make an important contribution of ascorbic acid to the diet during the winter season, when the problem of getting adequate supplies of this vitamin is most difficult. Apples also contain a significant amount of iron. There is a 25 per cent loss of vitamin C in making applesauce. The loss is greater when apples are baked or made into pie.

Bananas are similar to apples in vitamin C value: they contain almost twice the iron. Bananas are a significant source of vitamin A.

Fresh strawberries are another food high in vitamin C, the range for eleven varieties being between 40 to 104 mg. per hundred grams. Thus one-half cup would supply from two thirds to more than the daily need for ascorbic acid.[24]

SUGARS, SYRUPS AND MOLASSES

White sugar contributes only calories to the diet. It is clear that the present large consumption of sugar is disadvantageous in that it means a smaller consumption of nutritionally superior foods. Brown sugar, corn syrup, honey, maple syrup and maple sugar contain small amounts of calcium and iron. Honey contains small amounts of some of the B vitamins and vitamin C. Molasses is an excellent source of both, 1½ tablespoons furnishing approximately one tenth the estimated daily adult allowance of calcium and one fifth the estimated daily adult need of iron. Sorghum supplies a lesser amount of calcium and about an equal amount of iron. Table blend syrups contain a significant but lesser amount of iron.

VEGETABLE OILS

Cottonseed, corn, soybean, peanut and olive oils and in lesser amounts other vegetable oils are consumed as shortenings, salad oils and margarines. The oils as such are sources only of energy and essential fatty acids. Many oleomargarines are now fortified with 15,000 international units of vitamin A per pound; they may also supply some vitamin D.

Tuberculosis Control.—Minimal, noninfectious cases of tuberculosis are private physicians' cases, not sanatorium cases. Indeed, the private practitioner can be a major force in the future control of tuberculosis in the communities of our country if he undertakes to participate in follow-up activities after surveys have been completed. Through his efforts, minimal tuberculosis can be checked and, in individual cases, never become serious. Under the physician's care, needless distress and tragedy can be avoided. As a consequence of his vigilance, the general practitioner can reduce the occurrence of deaths from tuberculosis.—Weber, F. J.: *Ohio Public Health,* February 1948.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., *Secretary*

CHLOROQUINE DIPHOSPHATE.—Aralen Diphosphate-Winthrop. — 7-chloro-4-(4-diethylamino-1-methylbutylamino) quinoline diphosphate.—$C_{18}H_{32}ClN_3O_8P_2$.—M. W. 515.88,

Actions and Uses.—Chloroquine diphosphate is highly active against the erythrocytic forms of Plasmodium vivax and Plasmodium falciparum. It does not prevent relapses in vivax malaria, nor will it prevent the establishment of vivax infection when administered as a prophylactic. It is, however, effective in vivax malaria as a suppressive agent and for the termination of acute attacks, significantly lengthening the interval between treatment and relapse.

In falciparum malaria, chloroquine diphosphate abolishes the acute attack and effects complete cure of the infection.

Chloroquine diphosphate has approximately three times the activity of quinacrine hydrochloride against standardized strains of P. vivax and P. falciparum.

Chloroquine diphosphate is rapidly and completely absorbed by the gastrointestinal tract. Some of it is excreted slowly in the urine. Considerable amounts are deposited in the organs and tissues, and it is concentrated in nucleated cells, particularly those of the liver, spleen, kidneys and lungs.

Dosage.—Chloroquine diphosphate is usually administered orally either before or after meals. For suppression of vivax malaria a weekly dose of 0.5 Gm. given at exactly seven day intervals is recommended.

Chloroquine diphosphate is metabolized in the body, but this occurs slowly and the drug may be detected in body tissues for more than a week after discontinuing medication. The drug is well tolerated in therapeutic doses and does not produce cinchonism or discolor the skin. However, there may be mild headache, pruritus, visual disturbances and gastrointestinal complaints following therapeutic doses. Blurring of vision and difficulty in focusing are occasionally observed following prolonged administration. None of the side reactions appears serious, and all have been of a reversible nature.

For treatment of acute attacks of malaria due to P. vivax and P. falciparum, an initial dose of 1 Gm. followed by an additional 0.5 Gm. after six to eight hours and a single dose of 0.5 Gm. on each of two consecutive days (total of 2.5 Gm. in three days) is sufficient to eradicate most infections with P. falciparum and to terminate an acute attack of vivax malaria. In the latter, freedom from clinical attacks may be maintained thereafter by administration of suppressive doses (0.5 Gm. weekly).

Tests and Standards.—

Chloroquine diphosphate occurs as a white, crystalline powder possessing a bitter taste. It melts in the range 193 to 195 C. Two modifications of chloroquine diphosphate are obtainable. The second form melts at 215 to 218 C. It is freely soluble in water and practically insoluble in alcohol, benzene, chloroform and ether. The *pH* of a 1 per cent solution is about 4.5.

Dissolve about 50 mg. of chloroquine diphosphate in 3 cc. of water. Add a few drops of ammonium molybdate-test solution: a white precipitate develops immediately.

Dissolve 20 mg. of chloroquine diphosphate in 20 cc. of water. Add 5 cc. of a saturated aqueous solution of picric acid: a yellow precipitate forms immediately Filter off the precipitate, wash with water and air-dry on the filter funnel: the product melts from 205 to 210 C. *(Caution!)*

Dissolve 0.25 Gm. of chloroquine diphosphate in 50 cc. of water. Add 1 cc. of strong ammonia solution and extract with two 30 cc. portions of cyclohexane. Evaporate the cyclohexane solution to dryness on the steam bath. Place the residual oil in a vacuum desiccator over phosphorus pentoxide and allow to stand over night to permit crystallization: the solid material melts at a temperature of 87 to 90 C.

Dry about 0.25 Gm. of chloroquine diphosphate, accurately weighed, in vacuum over phosphorus pentoxide at room temperature for forty-eight hours: the loss in weight does not exceed 2 per cent.

Dissolve about 0.2 Gm. of chloroquine diphosphate, accurately weighed, in 50 cc. of water. Dissolve 1.5 Gm. of bismuth oxynitrate in 10 cc. of nitric acid and dilute to 100 cc. with water. Add 50 cc. of the bismuth solution to the solution of chloroquine diphosphate. Digest for two hours on the steam bath, filter into a tared Gooch crucible and wash with dilute nitric acid (2 cc. to 100 cc.). Wash successively with water, alcohol and ether. Dry in an oven at 100 C. for two hours: the phosphorus content is not less than 11.8 per cent or more than 12.25 per cent.

Weigh, accurately, about 0.2 Gm. of chloroquine diphosphate. Dissolve in 50 cc. of water, transfer to a separatory funnel. Add 5 cc. of ammonium hydroxide and extract with 25, 20, 15, 10 and 10 cc. portions of ether. Drain the combined ether extracts through a cotton pledget into a 100 cc. tared beaker. Evaporate the solution on the steam bath to dryness and finally heat at 100 C. for thirty minutes: the residue, calculated to chloroquine diphosphate, is not less than 98 per cent or more than 102 per cent.

CHLOROQUINE DIPHOSPHATE TABLETS

Grind ten tablets in a mortar. Weigh, accurately, about 0.3 Gm. of the pulverized tablets. Dissolve in about 50 cc. of water, filter and wash the residue with about 20 cc. of water. Transfer to a separatory funnel, add 5 cc. of ammonium hydroxide and extract with 25, 20, 15, 10 and 10 cc. portions of ether. Drain the combined ether extracts through a cotton pledget into a 100 cc. tared beaker. Evaporate the solution on the steam bath to dryness and finally heat at 100 C. for thirty minutes: the residue, calculated to chloroquine diphosphate, is not less than 95 per cent or more than 105 per cent.

WINTHROP-STEARNS, INC., NEW YORK

Tablets Aralen Diphosphate: 0.25 Gm.

U. S. patent 2,233,970 (March 4, 1941; expires 1958).
U. S. trademark registration pending.

ASCORBIC ACID See New and Nonofficial Remedies, 1947, p. 517).

The following additional dosage form has been accepted:

THE NATIONAL DRUG COMPANY, PHILADELPHIA

Tablets Ascorbic Acid: 100 mg.

ESTRONE (See New and Nonofficial Remedies, 1947, p. 341).

The following additional dosage forms have been accepted:

ABBOTT LABORATORIES, NORTH CHICAGO, ILL.

Estrone in Oil: 10 cc. vials containing 1 mg. (10,000 international units) in peanut oil. Preserved with 0.5 per cent chlorobutanol.

Aqueous Suspension Estrone: 1 mg. in 1 cc. ampuls (10,000 international units) and 5 mg. in 1 cc. ampuls (50,000 international units). Each cubic centimeter contains estrone crystals in aqueous suspension with isotonic sodium chloride solution, stabilized with acacia.

PERTUSSIS IMMUNE SERUM (Human) (See New and Nonofficial Remedies, 1947, p. 440).

The following dosage form has been accepted:

HYLAND LABORATORIES, LOS ANGELES

Pertussis Immune Serum (Human): Vials containing vacuum-dried powder representing 20 cc. of pertussis immune serum (human) preserved with merthiolate 1:35,000. Each vial is packaged with a 10 cc. vial of sterile distilled water.

NICOTINAMIDE (See New and Nonofficial Remedies, 1947, p. 514).

The following additional dosage form has been accepted:

AMERICAN PHARMACEUTICAL CO., INC., NEW YORK

Tablets Nicotinamide 100 mg.

ESTROGENIC SUBSTANCES (See New and Nonofficial Remedies, 1947, p. 343).

The following dosage forms have been accepted:

GEORGE A. BREON & CO., INC., KANSAS CITY, MO.

Solution Estrogenic Substances in Oil with Chlorobutanol 3 per Cent: 30 cc. vials containing the equivalent of 10,000 international units per cubic centimeter in sesame oil. Preserved with 3 per cent chlorobutanol.

FORBES LABORATORIES, NEW YORK

Solution Estrogenic Substances in Oil: 1 cc. ampuls and 10 cc. and 30 cc. vials containing 10,000 international units and 1 cc. ampuls and 10 cc. and 20 cc. vials containing 20,000 international units in sesame oil. Preserved with 0.5 per cent chlorobutanol.

SATURDAY, APRIL 17, 1948

HOSPITAL NUMBER POSTPONED

Under normal conditions this issue of THE JOURNAL would be the annual Hospital Number. However, the absence from their work of the compositors employed by the American Medical Association continues, and it is necessary to postpone the Hospital Number until arrangements can be made to set up the large tables of statistics that special number contains. It is hoped this can be done by late May or early June.

BAGASSE DISEASE OF THE LUNGS

Sugar cane from which the juice has been extracted is called bagasse. The product is stored in the open for months or years when it is broken, processed and pressed into various shapes for insulating building materials. The dust of the dried grass is an industrial hazard. The disease that follows its inhalation is known under the dubious name of bagasse or even more improperly, perhaps, as bagassosis[1] or bagasscosis.[2] Sodeman and Pullen[3] state that "Since the suffix 'osis' is properly added only to words formed from Greek roots and since we have as yet not been able to trace the term 'bagasse' to the Greek, we prefer the simple term 'bagasse disease of the lungs."

Bagasse disease of the lungs is characterized by cough, dyspnea and hemoptysis, night sweats, chills and intermittent fever. Roentgenologic examination of the chest shows mottling of both lungs, like that of miliary tuberculosis. The disease commences insidiously. The pulmonary reactions incited by the inhalation of bagasse dust are reversible and complete resolution may occur. Because the disease is seldom fatal, only rare opportunities have thus far been presented to determine the histologic changes in the lungs.

Investigations of this sort have been limited to a single necropsy and to the removal of a few particles of tissue for biopsy, The lesions so far described consist of localized pneumonic areas composed of foam cells together with foreign body reactions around bagasse fibers.

The cause of bagasse disease is still obscure. Some investigators believe it is either a fungus or a bacterial infection, the causative agents being introduced on the surface of the inhaled dust. Others contend that it is a virus disease and still others that it is an allergic response to the presence of bagasse material.

Gerstl, Tager and Marinaro[4] have approached the subject experimentally and the results are suggestive. Suspensions of five lots of bagasse were administered intravenously, insufflated into the trachea or injected into the skin of rabbits and guinea pigs. Animals receiving intravenous injections of bagasse in suspension rapidly became ill or died. When, however, the dust was autoclaved similar amounts of the suspension could be given without apparent ill effects. The lungs and other viscera of the animals receiving fresh bagasse suspension showed extensive foci of necrosis and cellular reactions. In addition, the presence of mycelia and spores in the damaged organs served as an indication of the nature of the infective agent. Animals that received injections of autoclaved bagasse revealed only small granulomas in the lungs of the foreign body type. These results suggest that bagasse disease of the lungs is caused by a fungus and that the dust itself is relatively innocuous.

THE DEVELOPMENT AND PROGRESS OF NEUROSURGERY

In his centennial address before the Section on Nervous and Mental Diseases of the Annual Session of the American Medical Association at Atlantic City, N.J., June 12, 1947, Stanley Cobb reviewed progress in the previous hundred years in neurology, psychiatry and neurosurgery.[1] In 1847 specialisation in medicine was just beginning. While psychiatry was already developing, neurology was in the earliest stages and neurosurgery did not exist. After instructive sketches of the advances in the knowledge of the nervous system, its structure, physiology and diseases, Cobb considered neurosurgery, which did not begin until about 1900. The technics of neurosurgery—asepsis, anesthesia and hemostasis--were not sufficiently developed earlier, which was the case also with the clinical localization of lesions within the brain and the cord.

---

[3] Sodeman, W.A., and Pullen, R.L.: Bagasse Disease of the Lungs, Arch. Int. Med, 73:365, 1944.

[4] Gerstle, B., Tager, M., and Marinaro, N. A., Pathogenicity of Bagasse, Arch. Path. 44: 343, 1947.

[1] Cobb, S.: One Hundred Years of Progress in Neurology, Psychiatry and Neurosurgery, Arch. Neurol. & Psychiat. 59: 63-98 (Jan.) 1948.

According to Cobb, Godlee in 1884 removed the first brain tumor " localized scientifically." Trepanning was done by the neolithic man; Hippocrates used the trephine with occasional success, and by 1890 more and more successful operations were performed on the brain. Sir Victor Horsley (1857-1916) is listed as the first neurosurgical specialist. He devoted his life to neurosurgery, for which he prepared himself by operations on dogs and monkeys. He was a great source of inspiration and added much to the understanding of cerebral physiology. According to present standards his technic seems rather rough and the care that his patients received seems somewhat primitive.

After due mention of other pioneers in neurosurgery, Cobb called special attention to Harvey Cushing (1869-1939), who, besides guiding neurosurgery into a specialty of the first order, advanced greatly the knowledge of brain tumors, their clinical manifestations, their structure and origin, their effects on nervous functions and their surgical treatment. Cushing removed his 2,000th brain tumor in May 1931 and operated for the last time in November 1932.

Neurosurgery has expanded greatly since pioneer days. A notable number of physicians have devoted themselves to the long and difficult training in the technics and the background of neurosurgery. The 1939 meeting of the Harvey Cushing Society was attended by thirty-seven members. According to Cobb two hundred and thirty-one surgeons have been approved by the board of neurosurgery. Frontal leukotomy has increased the understanding of the functions of the frontal areas of the brain, and there seems to be good reason to expect new advances in neurology and psychiatry as neurosurgery extends.

Cobb closed his valuable review with the following paragraph:

> One hundred years from now, when some neurologist of the twenty-first century gives this historical review for the bicentenary of the American Medical Association, he will tell of many advances with the new technics of physics and chemistry. Words we are just learning to use will be commonplace, and new terms and concepts that we could not understand will be used. Our present theories will seem primitive. Nevertheless, the golden years of anatomy in the late nineteenth century will not be forgotten. The resurgence of neurophysiology in the beginning of the twentieth century will remain a great epoch. The development of neurosurgery will stand as an example of hard-earned medical progress by brilliant and courageous men.' And, unless we pay more heed to social psychology and to the facts that psychiatry is gleaning from the study of interpersonal relations, there will be no meeting of the American Medical Association in 2047!

Current Comment

HEMOCONCENTRATION AND GASTRIC ULCER

Hemoconcentration following extensive superficial burns was believed by Kapsinow[1] to be the etiologic factor in the production of gastric and duodenal lesions (Curling's ulcer). Friesen and Wangensteen[2] of the Department of Surgery, University of Minnesota Medical School, studied the question by experiments on dogs under deep intravenous sodium pentobarbital anesthesia (15 mg. per pound). In 12 of 14 dogs subjected to burns accompanied by the administration of histamine hemoconcentration developed, the hematocrit reading rising from an average of 44 per cent to an average of 55.7 per cent. Readings as high as 65 to 72 per cent were recorded in certain dogs. All 12 dogs showed congestion of the mucous membrane of the stomach and duodenum. Nine of them showed definite Curling's ulcer, 5 bleeding and 3 perforating. The 2 dogs in which increased concentration of the blood failed to develop did not demonstrate gastric or duodenal abnormality. In a second group of dogs subjected to burns accompanied by the administration of histamine in beeswax, attempts were made to prevent hemoconcentration by controlled intravenous instillations of plasma. In all cases in which blood concentration was maintained at a normal level, gastric or duodenal abnormality did not appear. Similar though less pronounced results were obtained in dogs in which increase in gastric secretion was not produced by histamine injection. From these results increased concentration of the blood following extensive superficial burns is the dominant etiologic factor in the production of Curling's ulcer. Gastrointestinal abnormalities following such burns can be prevented by adequate antihemoconcentration therapy.

Official Notes

AMEND BROADCAST PROGRAM

Due to cancellation of time by the National Broadcasting Company for April 24, the program of the American Medical Association Network series, "Doctors Today," scheduled for that date will be broadcast May 1. Subsequent programs will be broadcast a week later than originally scheduled in the March 27 issue of THE JOURNAL. The amended program is as follows:

May 1, 1948	Child Guidance
May 8, 1948	Health for Every Citizen
May 15, 1948	Human Brucellosis

Washington Letter

(From a Special Correspondent)

April 15, 1948.

Scheele Testifies Before Committee

One of the first official acts of Dr. Leonard A. Scheele, following his induction as Surgeon General of the Public Health Service, was to testify before a congressional committee. He told the House Committee on Interstate Commerce that 54,000,000 Americans live in communities which lack full time local health services. In accepting his appointment Dr. Scheele said: "The health of the American people and their health resources cannot and must not become a monopoly, either of governments, private enterprise or charitable organizations. Each of these great institutions has made incalculable conibutions to American Health. The constituent groups and organizations within them must endure and grow in wisdom, strength and efficiency."

Outline Plan to Replace Physicians

Dr. Paul Magnuson, medical director of the Veterans Administration, reported that a plan has been worked out to replace the thirteen hundred physicians on loan from the Army and Navy who are expected to leave the agency this summer. Outgoing military physicians will be replaced by three year resident physicians. To assist the agency and simultaneously broaden opportunities for residents, prospective specialists will serve their final two years in veterans' hospitals, practicing under the supervision of certifified consultants. The agency now has a residency program covering the first three years of the specialty apprenticeship. The advanced program will provide salaries from $4,100 to $7,000 annually.

Approves Allowances For Disabled Veteran's Dependents

The House Veterans Committee unanimously approved a bill to give $61,800,000 in special allowances to dependents of 130,700 veterans with disabilities of 60 per cent or more. The bill, if finally approved, would for the first time establish benefits for dependents of disabled men. It would give these allowances to dependents of totally disabled veterans of World Wars I and II: wife, $30 a month; first child, $20; next two children, $15 each; dependent mother or father, $25 each. The allowances would be reduced for lesser disabilities.

Rider To Appropriations Bill Rejected By Committee

Representative Frank Keefe, Republican, Wisconsin, sponsored a civil rights rider to the appropriations bill which would have barred federal public health, hospital and vocational educational grants from states practicing racial discrimination. The defeated Keefe amendment read: "No part of the appropriations provided for in this act shall be paid as grants to any state or educational institution in which, because of race, color or creed, discriminatory practices deny equality of educational opportunity or employment to pursue such educational courses or employment as are provided for by such grant." The rider would have denied federal subsidies from state universities or hospitals that do not admit Negroes. Suspension of the rider is said to have removed another potential source of controversy in the present civil rights issue over which Southern Democrats threaten to withdraw from the party and have taken steps to remove President Truman's name from state ballots.

Experts Say Physicians Are Unprepared For Atomic Attack

In a recent address here, Rear Admiral Clarence J. Brown, assistant chief of the Bureau of Research and Medical Military Specialties, declared that the nation's physicians are unprepared for the emergency of an atomic bomb attack in the event of another war. He advocated that all medical practitioners take training in military aspects of medicine. The general public, he said, "may possibly derive some comfort from the hope that threat of retaliation might minimize an enemy attack." "Not so of the medical profession," he said; "its work begins before any retaliation. Long before the retaliation bombs are received by the enemy, we shall be confronted in our great cities by the world's greatest catastrophe, such utter devastation, such unexampled human misery as transcends the imagination. During the immediate hours and days which follow, who will bear the burden of the professional care of the survivors? Who will set up the sanitary controls, provide the mass innoculations, insure the safety of food and water supplies, and direct the diagnosis and treatment of those who are suffering insidious radiation illness?"

STATE LEGISLATION

Kentucky

Bills Enacted.--H.447 was approved March 25. Relating to training of Negro nurses and doctors, it provides that nothing in the law shall be construed to prohibit the giving of instruction in nursing, medicine, surgery, or other related courses of graduate grade or on the professional level, within any hospital, if the governing body of the hospital, by a majority vote of its of its members, so elects.

S.105 was approved March 29. It provides for the creation of a medical research commission to provide for a program of research in the fields of medicine, surgery and allied sciences, preventive medicine, control of diseases and all other features of medicine and surgery that affect the health and welfare of the people of the state.

GOVERNMENT SERVICES

ARMY

NEW PROFESSIONAL TRAINING OPPORTUNITIES

A greatly expanded professional training program for regular and reserve medical officers of the Army has been announced by the Surgeon General. The program calls for one thousand, nine hundred new physicians in the Regular Army and an increasing number of volunteer reserve officers on active duty. It is designed to give many more Army physicians the training to meet requirements for certification by American Specialty Boards, and to further integrate civilian and military medicine. The following five major aspects of the new program were described by the Surgeon General:

1. Physicians already resident in civilian hospitals are now eligible for commissions in the Regular Army. Those commissioned may continue their residencies with full pay and allowances and will be assigned by the Army to the civilian hospital in which they are already resident. Even in the event of a major emergency, residents will complete their training, if it is at all possible. Chances of continuing training for these men will be at least as good as those of civilian physicians in resident training. The Surgeon General's Office will commission three hundred residents under this aspect of the program in 1948, three hundred in 1949-1950 as senior residents, one hundred as residents and a hundred and fifty as junior residents.

2. Civilian interns are now eligible for commissions in the Army medical corps reserve and may continue their internship with full Army pay and allowances. Those so commissioned will undertake to accept a commission in the Regular Army on completion of their internship, and will then be permitted to compete for Army residencies in either Army or civilian hospitals. In 1948 and again in 1949, three hundred interns will be included in this phase of the training program.

3. During 1948, five hundred younger physicians will be commissioned and assigned to duty at Army hospitals in order to compete for two hundred and sixty residencies in both Army and civilian hospitals. Competitive examinations will begin in either September or October, 1948. These residencies are apportioned among the various specialties according to the needs of the Army medical corps. Resignation of officers commissioned under this phase of the program will not be accepted within one year after the date of commission.

4. One hundred and fifty commissions in the grades of major, lieutenant colonel and colonel will be offered in 1948 and an equal number in 1949 to physicians who have completed their training. This aspect of the program is not limited to those men already certified as specialists, since outstanding officers for command and staff positions are needed as well as professional men. Applicants for those commissions in higher grades will not be considered for residencies or specialty training.

5. Active reserve service for specific positions and limited periods will be offered physicians who are not interested in a Regular Army career. Those who come into the service in this manner will not be eligible for residencies, but time spent in practice under this aspect of the program may receive recognition by the specialty boards.

The program is designed to attract to a Regular Army career medical talent of the highest caliber. One year of active duty as distinguished from training duty is expected for each year of training, whether the training is received in Army or civilian institutions. Resignations will not be considered until this obligation has been fulfilled.

Training continuous until completion of the requirements for Specialty Board certification is a definite aim of the program, the Surgeon General emphasized.

The program has been presented to the Council on Medical Education and Hospitals of the American Medical Association and to the Association of American Medical Colleges. Both bodies have officially recognized the value of the program in its entirety.

Information concerning any part of the program may be obtained from the Surgeon General's Office. Address requests to the attention of the Chief of Personnel, Surgeon General's Office, Department of the Army, Washington, D. C.

INSTITUTE OF PATHOLOGY

Members of the staff of the Army Institute of Pathology presented the following papers at the American Association of Pathologists and Bacteriologists and of the International Association of Medical Museums at Philadelphia in March:

Dr. Ira Gore (Veterans Administration), Morphologic Aspects of Disseminated Platelet Thromboses.

Dr. Webb Haymaker, Pathology of Herpes Simplex Encephalitis; Report on Three Proved Cases.

Dr. Lent C. Johnson, Histogenesis of Myositis Ossificans.

Dr. Hans F. Smetana, Histologic Lesions Encountered in Regional Enteritis.

The following lectures or seminars were given by members of the staff during February:

Dr. Elson B. Helwig at Georgetown University, Pigmentation.

Dr. Lent C. Johnson at Arlington Hospital, Va., Recent advances in Nephritis; and before the Alexandria Medical Society, Dynamic Pathology of Eclampsia.

Dr. Webb Haymaker at Mount Alto Hospital, Landry-Gullain-Barre Syndrome.

Lieut. John Schut at Walter Reed General Hospital, Hereditary Ataxias.

Dr. Ira Gore at Mount Alto Hospital Myocarditis.

THE ARMY WINTERED WELL

Throughout the past winter, the Army was in better health than during any like period for which comparable statistics are available. The average January hospital admission rate for the past quarter-century was a little over 14 per thousand troops per week, while the weekly rate for January 1948 was 9.4 per thousand; the February rate was 50 per cent lower than the average for the past twenty-five years. The normal peak load of illness in the Army, as elsewhere, occurs usually in February, due to the increase in respiratory infections. While the present year was no exception, influenza was an almost negligible quantity in the total illness, and other respiratory diseases added comparatively few cases.

OFFICERS REQUEST GRADUATE TRAINING

The following officers have requested graduate training, and their requests were approved at the meeting of the Advisory Board of the Bureau of Medicine and Surgery on March 11: Lieutenants (jg) Walter R. Holland, residency in anesthesia at the Naval Hospital, St. Albans, N.Y.; Neal D. Sanborn, residency in internal medicine at a naval hospital and William R. True, residency in ophthalmology at a naval hospital; Lieutenants Berwyn H. Force, course in internal medicine at the University of Pennsylvania; Robert K. Moxon, residency in internal medicine at the Naval Hospital, Philadelphia; William S. Stryker, residency in children's orthopedics at the Shriners Hospital for Crippled Children, Philadelphia, and David J. McMurray, residency in otolaryngology at the Naval Hospital, Philadelphia; Lieut. Comdr. Bruce M. Shepard, residency in surgery at the Naval Hospital, St. Albans, N.Y.; Comdr. Edward P. Irons, residency in otolaryngology, Naval Hospital, Philadelphia; James W. Gustin, Jr., residency in surgery at Naval Hospital, St. Albans, N.Y.; Joseph J. Timmes, course in surgery at the University of Pennsylvania and Shakeeb Ede, residency in surgery at the Naval Hospital, Long Beach, Calif.

RESERVE MEDICAL DIVISIONS

Naval Reserve volunteer medical divisions have been organized in Charleston, Huntington and Wheeling, West Virginia; the commanding officers are Captains Russel Kessel, William M. Strange and William M. Sheppe, respectively. Other divisions are expected to be organized at Bluefield and Parkersburg. The goal for each medical division includes seventy-five medical officers, fifty nurses, two hundred and fifty hospital corpsmen and fifteen medical service corpsmen.

NUMBER OF CASES OF SCRUB TYPHUS

Preliminary reports indicate that there were 6,850 cases of scrub typhus among Army personnel during World War II and that 280 persons died of the disease; during the same period the Navy reported 613 cases with 28 deaths. The Navy has developed a method for preparing a purified suspension of the causative organism, Rickettsia orientalis, which when used as a vaccine has protected animals against 20,000 times the amount of live organisms sufficient to kill 1 animal. The Navy considers it likely that this discovery will lead to the development of a vaccine that will prevent scrub typhus and also will be useful as a diagnostic aid. Scrub typhus is most prevalent in Japan, Formosa, Malaya and Burma.

AWARDS AND COMMENDATIONS

Dr. Edward A. Strecker

Dr. Edward A. Strecker, professor of psychiatry and head of the department of consultation, University of Pennsylvania, was awarded the Presidential Certificate of Merit at ceremonies held the evening of January 16 at the Naval Hospital, Philadelphia. Dr. Strecker received the award in recognition of his services as consultant to the Surgeon General of the Navy since May 6, 1943.

Commander William J. James

Comdr. William J. James, (MC), U.S.N., chief of the Neurosurgery Department, Naval Medical Center, Bethesda, Md., has been awarded the Bronze Star for meritorious service as medical officer on board the U.S.S. *Randolph* in action against the Japanese forces in the Pacific area from February 16 to July 26, 1945. Dr. James served as senior medical officer and flight surgeon on the *Randolph.* He graduated from St. Louis University School of Medicine in 1937 and entered naval service Aug. 14, 1939.

PUBLIC HEALTH SERVICE

DR. SCHEELE BECOMES SURGEON GENERAL

Dr. Leonard A. Scheele was sworn in as Surgeon General of the Public Health Service at ceremonies held Monday, April 5, in the Federal Security Agency auditorium, Washington, D. C. Dr. L. R. Thompson, a former Assistant Surgeon General, administered the oath of office; also attending were Dr. Thomas Parran, retiring Surgeon General, Oscar Ewing, Administrator of the Federal Security Agency, and representatives of the American Medical Association, medical schools and government agencies.

FULL TIME CANCER DETECTION CENTER

One of the first full time cancer detection centers in the United States is being operated by the cancer control branch of the National Cancer Institute, Public Health Service, as a demonstration unit at Hot Springs, Ark. The center is located in buildings of the Public Health Service rapid treatment center for venereal disease, whose patients it examines exclusively. The staff includes Dr. Byron E. Watts, chief, and other Public Health Service personnel: two physicians trained in cancer diagnosis at Memorial Hospital, New York; two medical officers trained in cytologic technic under Dr. George N. Papanicolaou, and a nurse officer who arranges for the follow-up of patients with lesions. The project is under the supervision of Dr. Allan Koplin, chief, Field Operation Unit, Cancer Control Branch. Specially trained clerical workers take a routine screening history, which is then amplified by the physician. By March 1, 800 patients, all women, had been given complete physical examinations and the cytologic test for cancer. Thus far 8 cases have been discovered. Examination of male patients will be started later.

CANCER RESEARCH FACILITIES

The National Advisory Cancer Council at a meeting in Washington, D. C., March 12 named twenty-one universities and hospitals as being in great need of more facilities to carry on desired scientific projects in cancer research. The council recommended that the $2,053,000 available in funds of the National Cancer Institute for the construction of nonfederal research facilities be stretched as far as possible and where most needed among the institutions named. More than $8,000,000 was involved in the requests favorably considered by the council. The two largest requests for construction grants that were recommended were $1,000,000 each to the University of California Medical School, Berkeley, and College of Physicians and Surgeons, New York, for construction and equipment for the Cancer Research Institute and the Cancer Research Laboratory, respectively.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

ARIZONA

State Medical Meeting. – The Arizona State Medical Association will hold its annual meeting May 19-21 at the Westward Ho Hotel, Phoenix. The guest speakers will be:

J. Dewey Bisgard, Omaha, Cancer-Ulcer Problem of the Stomach.
Jerome W. Conn, Ann Arbor, Mich., Management of Diabetic Coma.
Irvin E. Hendryson, Denver, Early Diagnosis of Poliomyelitis.

The Woman's Auxiliary will meet at this time.

CALIFORNIA

Typhoid Carrier in High School Cafeteria.--Twenty-one cases of typhoid fever, type C, occurred in high school students in Ukiah, Mendocino County, during January. Epidemiologic investigations by the California Department of Public Health have disclosed that the chief cook in the school cafeteria was a typhoid carrier. Control measures taken at the time of the outbreak included (1) pasteurization of the community's milk supply, (2) closing of the school cafeteria and (3) immunization of the entire high school student body.

Report of Eye Bank.—The Stanford Eye Bank reported March 12 that it had provided thirty-three corneas for eye graft operations during its first year of operation. All qualified eye surgeons on the Pacific Coast have been invited to make use of the facilities of the bank. Corneas collected and preserved by the eye bank are distributed without cost to either patient or surgeon, except for a small service fee for cost of handling the tissue. Information on the correct procedure for registration of donors can be secured by writing to the Stanford Eye Bank, 2398 Sacramento Street, San Francisco.

CONNECTICUT

Doctors Aid Vienna Patients.--An anonymous group of Greenwich physicians is aiding patients in a Vienna, Austria, hospital by providing, through the Greenwich Committee for Foreign Relief, drugs and instruments for the use of fellow professional men in the Austrian capital. Mrs. Samuel K. Meek, committee chairman, recently announced that a shipment prepared by the physicians themselves and sent through the committee has already arrived in Vienna, where a grateful official is utilizing most of it for the care of infants and children.

Yale to Sponsor Graduate Education.—The expansion of Yale facilities for graduate education for Connecticut physicians has been announced, and the appointment of Dr. William R. Willard, New Haven, assistant professor of public health, as associate dean in charge of graduate medical education. Dr. Willard graduated from Yale University School of Medicine, New Haven, in 1934 and received a doctor of public health degree in 1937. He has been deputy state health officer for Maryland and a surgeon of the U.S. Public Health Service. The Connecticut State Medical Society is cooperating in the establishment of the deanship. The expanded program has two aims; (1) provision for short and long refresher courses for Connecticut physicians, and (2) assistance to small Connecticut hospitals in training resident physicians who are preparing to become specialists

DISTRICT OF COLUMBIA

Personal.--Dr. W. Montague Cobb, associate professor of anatomy, Howard University College of Medicine, has been appointed head of the department of anatomy. He is a graduate of Howard University, 1929.

University Opens New Hospital. – George Washington University took possession of its new four hundred bed hospital March 19. The hospital occupies a city square, contains one hundred and twenty single and one hundred and eight double rooms, eighteen wards and forty beds for resident physicians and interns, six air-conditioned major operating rooms, and three smaller ones, nine air-conditioned delivery rooms, nurseries, noise abatement devices, and motion picture equipment to record operating room technics. A large amount of space will be devoted to laboratories and research units. Built at a cost of about $3,897,000, of which $2,820,000 was for construction and fixed equipment and about $850,000 for site acquisition, the outlay per patient bed, estimated on basic cost, was about $8,370. The university, which will staff the hospital, is providing movable equipment and furnishings to cost about $970,000.

ILLINOIS

Chest Physicians Meeting.—The annual meeting of the Illinois Chapter of the American College of Chest Physicians will be held at the Palmer House, Chicago, May 10. The guest speaker will be Dr. Roy A. Wolford, Veterans Administration, Washington, D. C., " The Program of the Veterans Administration on Diseases of the Chest. "

Chicago

Dr. Fulton to Lecture. – The fifth annual D. J. Davis Lecture on Medical History will be given by Dr. John F. Fulton, Yale University School of Medicine, New Haven, Conn., on April 28 in room 221 of the University of Illinois College of Medicine. His subject is " The Position of William Withering in the History of Scientific Medicine.

Annual Zeit Memorial Lecture.—The fifth annual Robert Frederick Zeit Memorial Lecture, sponsored by the Chi Chapter of Alpha Kappa Kappa, will be delivered by Dr. Irvine McQuarrie, professor of pediatrics, University of Minnesota, Minneapolis, in Thorne Hall at Northwestern University, Lake Shore Drive, April 22 at 4 p.m. Dr. McQuarrie, who recently made an extensive trip through the Orient, will speak on " Medical Problems and Practice in Japan. "

Society of Internal Medicine.—The April meeting of the Chicago Society of Internal Medicine will be held April 26 at the Drake Hotel at 8 p.m. A panel on "Massive Albumin Therapy in Disease of the Liver " will be presented by Dr. Robert M. Kark, Chicago, and the invited speakers, Drs. George J. Gabuzda, Chicago, Gordon R. Morey, Westchester, Ill., Robert E. Johnson, Tinley Park, Ill., and Mr. Frank C. Consolazio, Chicago. John S. Gray, Ph.D., Chicago, has been invited to speak on "The Physiology of Dyspnea. "

University Given Bassoe Portrait.—A portrait of the late Dr. Peter Bassoe was presented to the University of Illinois College of Medicine March 26 by the Central Neuropsychiatric Association. The portrait, painted by Oskar Gross, will be hung in the Quine Medical Library. Dr. Bassoe, who died Nov. 5, 1945, was the founder and first president of the Central Neuropsychiatric Association and was a member of a committee appointed by the late Governor Horner to draw plans for the establishment of the Illinois Neuropsychiatric Institute.

KENTUCKY

Society News.—The Jefferson County Medical Society on April 19 will hear Dr. Willard R. Cooke, professor of gynecology and obstetrics at the University of Texas Medical Branch, Galveston, Texas, on "Rationalism in Regard to Gynecologic Operations." He will speak at a dinner meeting at the Pendennis Club at 7 p.m. under the sponsorship of the Louisville Obstetrical and Gynecological Society

LOUISIANA

Alumni Organize.—At a meeting of the Louisiana State University School of Medicine, New Orleans, on March 18, the New Orleans District of the Medical Alumni Association was organized. About seventy-five of over three hundred and fifty alumni practicing in New Orleans were present to hear Dean Vernon Lippard discuss plans for expansion of the school. Officers elected were Dr. Jack R. Anderson, president, and Dr. Philip L. Cenac, secretary-treasurer. Meetings of the association are to be held quarterly.

Graduate Course in Basic Sciences. -- A graduate course in the basic sciences as applied to orthopedic surgery has been established at Tulane University of Louisiana School of Medicine, New Orleans. The course has been made available for the first time to physicians other than those associated with the orthopedic clinics at Charity Hospital, the Veterans' Hospital, Touro Infirmary and Tulane. Divided into four categories, physiology, pathology, bacteriology and anatomy, the course involves twenty-five weeks of instruction. Dr. Jack K. Wickstrom, instructor in orthopedics, is in charge of the course.

MASSACHUSETTS

Appoint Professor of Anatomy.—Dr. Arthur M. Lassek, head of the department of anatomy at the Medical College of the State of South Carolina, Charleston, since 1932, has been appointed Waterhouse professor of anatomy at the Boston University School of Medicine effective July 1, succeeding Dr. Jesse L. Conel, a member of the faculty of the university's school of medicine since 1923. Dr. Lassek previously taught at the University of Washington, Seattle; Northwestern University Medical School, Chicago, and the University of South Dakota School of Medical Sciences, Vermillion. Dr. Conel is retiring to continue his research on the development of the cerebral cortex at different ages of childhood. He plans to publish two more volumes on this subject and is working now on the child at the age of 14 months.

Multiple Sclerosis Clinics.--The first research clinic in a projected series to investigate multiple sclerosis was opened March 29 at the Beth Israel and Boston State hospitals, Boston, through a grant from the National Multiple Sclerosis Society. The Boston clinic will do research on the cause of the disease. Another clinic will be opened in the Albany Hospital, Albany, N. Y., where neurologists of Albany Medical College will cooperate with the New York State Department of Health in conducting the research. As soon as funds permit, the society will establish multiple sclerosis research clinics in leading cities across the country. The project of research clinics has been approved by the society's medical advisory board, of which Dr. Tracy J. Putnam, chief and attending surgeon, department of neurosurgery, Cedars of Lebanon Hospital, Los Angeles, is chairman, and Dr. Thomas M. Rivers, director of Hospital of the Rockefeller Institute for Medical Research, is vice chairman.

MISSOURI

The Seelig Fund.--Friends and colleagues of Dr. Major G. Seelig, St. Louis, have contributed funds to establish an annual lectureship in his honor at Washington University School of Medicine, St. Louis Dr. Seelig retired from the staffs of Washington University Medical School and Barnard Free Skin and Cancer Hospital in January. For twenty-seven years he has been a member of the faculty at the medical school, and for the past seventeen years he had been conducting cancer research. Dr. and Mrs. Seelig are living now at 54 Belleau Avenue, Atherton, Calif.

NEW JERSEY

Society News.--The New Jersey Proctologic Society recently elected Dr. Frank S. Forte, Newark, as president, and Dr. Urban R. Finnerty, Montclair, as secretary.

Organize Allergy Society.--Thirty-three charter members, representing all parts of the state, attended the organizational meeting of the New Jersey Allergy Society February 18 at the Academy of Medicine in Newark. Dr. Nathan Schaffer, East Orange, was elected president; Dr. William C. Greifinger, 31 Lincoln Park, Newark, secretary; and Dr. Frank L. Rosen, Newark, treasurer. Membership is open to physicians interested in the practice of allergy who are members of their county societies. The program of the first scientific meeting at the Academy of Medicine in Newark, May 12, will consist of a panel discussion of hay fever.

NEW YORK

Report of Committee on Cerebral Palsy.--The Joint Legislative Committee to Study the Problem of Cerebral Palsy has presented a report to the Legislature outlining a program to provide medical care, rehabilitation and special education for victims of the disease. The report recommended the establishment of seven centers for diagnosis and evaluation, three within New York City; revision of the formula for state aid to local school districts as it pertains to special education for the physically handicapped; the construction of a state hospital home for those too severely handicapped to live at home; an increase in the number of such cases to be cared for at the New York State Reconstruction Home at West Haverstraw; the development of an enlarged training center and a practice school for teachers of handicapped children at Buffalo State Teachers College; increased training of medical and other personnel needed for the full care of such children, and the immediate development of a plan to discover the names of all children in the state who suffer from orthopedic handicaps. Assemblyman Abraham Schulman Rochester, chairman of the committee, reported that the number of known cases of cerebral palsy among children in the state is 6,000.

Dr. Claude H. Barlow Awarded Certificate of Merit.—The President of the United States has awarded the Certificate of Merit to Dr. Claude H. Barlow, formerly of Trumansburg, for outstanding fidelity and meritorious conduct in aid of the war effort against the common enemies of the United States and its allies. Dr. Barlow went to Egypt in 1929 at the request of the Rockefeller Foundation to conduct research on bilharziasis. He also found that snails common to Egyptian canals and ponds are host to the Bilharzia (Schistosoma) parasite. During the recent war he infected himself with the organism in an effort to find a cure for the disease.

New York City

Personal.--At the January meeting of the Pan-American Ophthalomological Association in Havana Cuba, Dr. Arthur A. Knapp read a paper on "Treatment of Blinding Diseases of the World."

Residencies Available.--The new psychiatric division of the Kings County Hospital, Brooklyn, has a number of residents' positions available for appointment together with opportunities available for degrees in graduate work. The hospital is affiliated with Long Island College of Medicine. The standard resident's salary is $1,560 with maintenance. For information address the director of psychiatry, Dr. Sam Parker, Kings County Hospital, Albany Avenue and Winthrop Street.

Appointments and Promotions.--The following appointments to the faculty of New York University College of Medicine have recently been made: Thomas N. Graham, New York, assistant clinical professor in the department of dermatology and syphilology; Edgar Lawrence and Harry F. Wechsler, New York, assistant clinical professors in the department of medicine; Isidor C. Rubin, Hempstead, N. Y., clinical professor in the department of obstetrics and gynecology; Alfred J. Vignec, New York, clinical professor, department of pediatrics; Allan L. Grafflin, Boston, research associate, department of pharmacology; L. Corsa Reid, New York, associate professor, department of physiology, and William Watson, New York, associate professor, department of physiology. In the postgraduate division appointees from New York include Ira I. Kaplan, clinical professor, and Rieva Rosh, assistant clinical professor of radiology; Bela Mittelman, assistant clinical professor of psychiatry; Sidney Rubenfeld, associate clinical professor of radiology, and Charles R. Rein, associate clinical professor of dermatology and syphilology.

Promotions were as follows: Israel S. Freiman to assistant clinical professor, department of neurology; William M. Dick, associate clinical professor, and Miles Atkinson, assistant clinical professor, department of otorhinolaryngology; Charles Gottlieb, professor of radiology and chairman of the department; William P. Anslow Jr. and Laurence G. Wesson, assistant professors, department of physiology; George G. Deaver, professor of clinical rehabilitation, department of rehabilitation and physical medicine.

Manager of Toxicology Department.--Dr. Arthur G. Cranch retired January 1 as manager of the industrial toxicology department of Union Carbide & Carbon Corporation after twenty-eight years' service with the organization and is being retained as a medical consultant on a part time basis. Dr. Thomas W. Nale, New York, assistant manager of the department for two years, succeeds Dr. Cranch.

Society News.--The Brooklyn Urological Society has recently elected Dr. Frank C. Hamm, Brooklyn, president, and Dr. Harold B. Hermann, Brooklyn, secretary-treasurer.

OHIO

Seminar in Dermatology.--The Society of General Physicians of Cincinnati in collaboration with the Department of Dermatology, University of Cincinnati, will offer a seminar on the treatment of skin disease May 4-27, consisting of sixteen hours of lectures, demonstrations and case presentations. Thirteen members of the department will present the course. Lectures will be so given at the Cincinnati General Hospital that patients may be brought from the dermatology wards to the classroom.

TEXAS

Fund for Cancer Research.--The Damon Runyon Cancer Research Fund and the Variety Club Foundation of Texas recently gave jointly $100,000 to Southwestern Medical Foundation.

Dr. Williams Honored.--Dr. J. Rice Williams, Houston, was guest of honor at a meeting of associates and friends in Houston January 18. A service pin was presented to him in recognition of his fifty-four years as a member of the medical profession; in addition, he was cited for his work in civic affairs. Dr. Williams graduated from the University of Tennessee College of Medicine, Memphis, in 1894 and has practiced in Houston since 1904; since 1938 he has been speaker of the house of delegates of the state medical association.

Appoint Director of Cancer Hospital.--Dr. Charles L. Spurr, formerly on the faculty of the University of Chicago, has been appointed internist and director of the M. D. Anderson Hospital for Cancer Research, Houston. He was graduated from the University of Rochester School of Medicine and Dentistry in 1940 and was instructor at the University of Chicago for four years before serving in the U. S. Navy.

Dr. Gilbert H. Fletcher, who made a tour of European hospitals to observe methods of radiation therapy, has been appointed radiotherapist at the hospital. He was graduated from the University of Brussels in 1941, was an instructor at Cornell University Medical College, New York, from 1941 to 1945 and was radiologist in the United States Army from 1945 to 1947.

WEST VIRGINIA

State Medical Association Meeting.--The annual convention of the West Virginia State Medical Associatiin will be held at the Hotel Prichard, Huntington, May 10-12. An innovation will be round table breakfasts at which matters of general interest will be discussed. Guest speakers will be:

MONDAY

J. Warrick Thomas, Richmond, Va., Cutaneous Allergies.

Henry M. Goodyear, Cincinnati, Use of Chemotherapy and Antibiotics in the Treatment of Upper Respiratory Infections.

John B. Barnwell, Washington, D.C., Streptomycin and Tuberculosis.

Jean S. Felton, Oak Ridge, Tenn., Industrial Medicine.

Sophia J. Kleegman, New York, Diagnosis and Treatment of Infertility in Women.

TUESDAY

Perrin H. Long, Baltimore, Treatment of Infectious Hepatitis.

Emil Novak, Baltimore, Management of the Menopause.

Francis F. Schwentker, Baltimore, Pneumonia in Children.

J. Edwin Wood, Charlottesville, Va., Use of Low Sodium Diets in Treatment of Hypertension.

Russell L. Haden, Cleveland, Gout.

George F. Lull, Chicago, Secretary and General Manager, American Medical Association, Trends in Medical Service.

WEDNESDAY

Austin I. Dodson, Richmond, Va., Recent Advances in Urology.

Miller Francis Turney, Brooklyn, Cervical Disks.

Fred S. Rankin, Lexington, Ky., Surgical Treatment of Cancer of the Lower Gastrointestinal Tract.

J. Steward Rodman, Philadelphia, Carcinoma of the Breast.

The annual meeting of the Woman's Auxiliary will be held at the Frederick Hotel.

GENERAL

Hearing Society Changes Address.--The American Hearing Society, which has been housed for twenty-five years in the Volta Bureau Building, 1537 Thirty-Fifth Street N.W., on April 1 moved to 817 Fourteenth Street N.W., Washington, D.C.

Society News.—At the annual session of the American Academy of Pediatrics, Dallas, Texas, in December, Dr. John A. Toomey, Cleveland, was installed as president. Dr. Clifford G. Grulee, Evanston, Ill., continues as secretary.

Pharmaceutical Convention in Cuba. — The convention of the American Pharmaceutical Manufacturer's Association met April 12-14 at the Hotel Nacional de Cuba, Havana. The association's research award was presented to Dilworth Wayne Woolley, Ph.D., of the Rockefeller Institute, for his scientific achievements in nutrition. Dr. Roscoe L. Sensenich, South Bend, Ind. President-Elect of the American Medical Association, and Dr. Austin Smith, Chicago, Secretary of the Council on Pharmacy and Chemistry, discussed basic research of drug therapy.

Meeting of American Hearing Society.--The National Conference of the American Hearing Society will be held at the William Penn Hotel, Pittsburgh, May 19-22 under the presidency of Dr. C. Stewart Nash. Physicians speaking at the conference include:

Dean M. Lierle, Iowa City, Recent Advances in the Medical Treatment of Deafness.
Morris Fishbein, Editor, THE JOURNAL, Chicago, Is It Worth Hearing?
Emily A. Pratt, Washington State Department of Health, Prevention and Conservation of Hearing.

Among other subjects to be discussed are goals of group activities in hearing societies, hearing aid advisory centers, aural rehabilitation of adults and educational program for children with a hearing loss.

International Congress on Obstetrics and Gynecology.—The American Committee on Maternal Welfare in conjunction with the fourth American Congress will sponsor an International Congress on Obstetrics and Gynecology at the Hotel Pennsylvania, New York, May 14-19, 1950. Preliminary plans include a program in which each morning will be devoted to formal presentation and discussion of a general topic and each afternoon will be given over to round table and informal discussion of the subjects. Clinics will be developed in the medical centers of the country so that foreign visitors may acquaint themselves with the advances of American institutions. Inquiries should be addressed to the general chairman, Dr. Fred L. Adair, 24 West Ohio Street, Chicago 10.

Student Health Association. — The American Student Health Association will hold its annual meeting May 6-8 at the Hotel Statler, Detroit, under the presidency of Dr. Harry D. Lees, Philadelphia. Among the speakers will be:

Joseph A. Johnston, Detroit, Metabolism of Adolescence.
Robert B. Clarke, Ann Arbor, Mich., Neurologic Problems of College Students.
Donald M. Pillsbury, Philadelphia, Management of Acute Eruptions of the Skin.
E. Lee Shrader, St. Louis, and William G. Beadenkopf, Chicago, Influenza Vaccine.
Chris J. D. Zarafonetis, Ann Arbor, Mich., Infectious Mononucleosis.

A panel discussion of "The Changing Problems of Administration in Student Health Services" will conclude the program.

Life Insurance Medical Research Fund.--Thirty-one hospitals, medical colleges and research clinics in eighteen states and Canada will share $484,790 in grants from the Life Insurance Medical Research Fund during 1948 for research in heart disease. In addition, fourteen individual physicians will receive $52,600 in fellowships, two of them for work outside their country. Fellowship stipends vary from $2,500 to $4,000. The awards bring the total sum made available for aid to medical research by the Life Insurance Medical Research Fund since its organization in December 1945 to approximately $1,800,000. The fund is supported by one hundred and forty-nine life insurance companies in the United States and Canada and is administered through a board of directors representing the life insurance business and an advisory council of medical research experts. Dr. Francis B. Dieuaide, clinical professor of medicine, Columbia University College of Physicians and Surgeons, is the scientific director.

Courses for Medical Record Librarians.—A second workshop for registered record librarians is to be held in Denver May 24-28 at the Cosmopolitan Hotel. This will be presented by the Extension Course Division of the American Association of Medical Record Librarians with the cooperation of the University of Colorado Medical Center and the Colorado Association of Medical Record Librarians. A regular one week extension course will be given at St. Louis University, St. Louis, from June 14-18. This course is designed to present fundamentals for proper understanding of record work, and to assist those who are of necessity working with the Standard Nomenclature of Disease without having received training in its use. Enrolment is open to all persons working in the medical record department of a hospital. Further information about either of these courses may be obtained from Mrs. Edna Huffman, Field Representative, Extension Course Division, American Association of Medical Record Librarians, 22 East Division Street, Chicago 10.

Drs. Taussig and Blalock to Receive Award.--The 1948 Passano Foundation award will be presented to the Taussig-Blalock team which developed the operation popularly known as the "blue baby operation". Presentation of the $5,000 cash award will be made June 23 at the Palmer House, Chicago, during the Annual Session of the American Medical Association. Dr. Helen B. Taussig is associate professor of pediatrics and Dr. Alfred Blalock is professor of surgery at Johns Hopkins University School of Medicine, Baltimore. Since this operation was first undertaken in November 1944 more than 600 patients drawn from all parts of the world have been operated on at Johns Hopkins Hospital alone.

The Williams & Wilkins Company of Baltimore established the Passano Foundation in 1944 to aid in the advancement of medical research, especially research which promises clinical application.

Marriages

MARTIN S. KLECKNER Jr., Allentown, Pa., to Miss Barbara A. Luse of Oil City, February 7.

DAVID LATHAM TABER, Rockville Centre, N. Y., to Miss Jean Dennison of Gloversville, Dec. 17, 1947.

CLARENCE E. PHILLIPS, Sunbury, Pa., to Miss Jean R. Kiger, of Northumberland, at Williamsport, Md., Dec. 28, 1947.

DAVID J. ROSE to Miss Edith R. Sprung, both of New York, February 15.

Deaths

Midian Othello Bousfield ⊕ Chicago; born in Tipton, Mo., Aug. 22, 1885; Northwestern University Medical School, Chicago, 1909; past president and since 1934 chairman of the commission on hospitals and medical education of the National Medical Association; fellow of the American Public Health Association and of the Institute of Medicine of Chicago; first Negro member of the board of education and former director for Negro health of the Rosenwald Fund; served as consultant to the U.S. Children's Bureau and the Chicago Board of Health; a member of advisory committees to various national, state and local government agencies; formerly a member of the planning committee, White House Conference on Children; in the field of social work served the Chicago and the National Urban League and the Y.M.C.A.; vice president and medical director of the Supreme Liberty Life Insurance Company; member of the board of trustees of Provident Hospital; during World War II organized Station Hospital 1 at Fort Huachuca, Ariz., of which he became a commanding officer; for his services received the Legion of Merit; retired Nov. 9, 1945 with the rank of colonel; died February 16, aged 62, of angina pectoris.

Thomas Dwight Sloan, Charlottesville, Va.; born in Ripley, Tenn., Dec. 6, 1879; University of Virginia Department of Medicine, Charlottesville, 1909; instructor in chemistry at the University of Virginia from 1905 to 1909; engaged in medical missionary work in Nanking, China, where he served as professor of clinical medicine at the University of Nanking and superintendent of the University Hospital; medical superintendent of the Peking Union Medical College Hospital from 1922 to 1925; in 1925 became assistant director in charge of the Lakeside Hospital in Cleveland and later superintendent of the New York Post-Graduate Medical School and Hospital in New York; formerly medical superintendent of the Flagler Hospital in St. Augustine, Fla.; died January 10, aged 68.

Franklin Ramsdell Hughes ⊕ Cape May, N.J.; born in 1879; Hahnemann Medical College of Philadelphia, 1906; past president of the Cape May County Medical Society; during World War I served on the county advisory board; an examining physician on a local board of the selective service during World War II; formerly county coroner; medical examiner for the schools of Cape May; associated with the boards of health of the lower township West Cape May and Cape May for many years; medical officer in charge of the U.S. Public Health Service Relief Station from 1926 to 1945; on March 25, 1945 awarded an honorary degree of Doctor of Science by his alma mater; died in the Hahnemann Hospital, Philadelphia, February 5, aged 68, of aneurysm of the aorta.

Edwin Hulme McIlvain, Philadelphia; born in Millville, N.J., in 1887; Temple University, School of Medicine, Philadelphia, 1912; member of the American Medical Association; since 1915 medical director of the Budd Company; for many years lecturer on medical jurisprudence at his alma mater; a director of the Philadelphia Health and Tuberculosis Association; a vice president of the Tioga National Bank; a member of the city chamber of commerce; died January 15, aged 60, of hypertensive cardiovascular renal disease.

John E. Womack ⊕ Staunton, Va.; Medical College of Virginia, Richmond, 1909; served as secretary treasurer of the Augusta County Medical Society; during World War I a captain in the medical corps of the U. S. Army and during World War II chairman of the medical examining board of the local selective service board; at one time city health officer; affiliated with the King's Daughters' Hospital, where he died January 7, aged 65, of cerebral hemorrhage, arteriosclerosis and hypertension.

Robert Herbert Wright, Newton Center, Mass.; University of Virginia Department of Medicine, Charlottesville, 1900; member of the American Medical Association and of the Medical Society of Virginia; formerly associate professor of ophthalmology at the Medical College of Virginia in Richmond; fellow of the American College of Surgeons; formerly on the staff of the Stuart Circle Hospital in Richmond; died Dec. 22, 1947, aged 68, of coronary thrombosis

Thomas Bayson Aycock ⊕ Baltimore; University of Maryland School of Medicine, Baltimore, 1924; professor of clinical surgery at his alma mater; member of the American Association for Thoracic Surgery and of the Southern Surgical Association; member of the founders group of the American Board of Surgery; affiliated with the Baltimore City Hospitals, Bon Secours Hospital and the University Hospital; died January 7, aged 52, of cerebral hemorrhage.

Linus Terrell Baker ⊕ Dixie, La.; University of Nashville (Tenn.) Medical Department, 1908; served on the staff of Highland Sanitarium in Shreveport; awarded the Silver Beaver posthumously by Norwela Council of Boy Scouts of America for outstanding service to boyhood; died suddenly January 26, aged 62, of heart disease.

William Hulbert Banks ⊕ Yakima, Wash.; Keokuk (Ia.) Medical College, College of Physicians and Surgeons, 1900; served on the staff of St. Elizabeth's Hospital; died Dec. 24, 1947, aged 73.

Louis Henry Behrens ⊕ St. Louis; Missouri Medical College, St. Louis, 1894; past president of the St. Louis Medical Society; fellow of the American College of Physicians; specialist certified by the American Board of Internal Medicine; affiliated with the Barnes, Deaconess, Jewish and DePaul hospitals; director of the Municipal Opera; died January 1, aged 79, of myocardial infarction.

Freeman Elisha Bennett, Belfast, Maine; Medical School of Maine, Portland, 1899; formerly a member of the state legislature; died Nov. 29, 1947, aged 77, of pulmonary edema and Parkinson's disease.

Charles Frank Boucek, Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1896; member of the staff of St. John's General Hospital; director of the Provident Trust Company; president of the Dixon Motor Company; died January 17, aged 72, of osteosarcoma.

Edward Sinnet Bowman, Davenport, Iowa; State University of Iowa College of Medicine, Iowa City, 1893; died January 4, aged 79.

Mary Alice Brosius, Washington, D. C.; Columbian University Medical Department, Washington, 1894; Southern Homeopathic Medical College, Baltimore, 1895; on the courtesy staff of the Homeopathic Hospital; died January 20, aged 89, of gastrointestinal hemorrhage.

Annual Meeting of British Medical Association

The next annual meeting of the British Medical Association will be held at Cambridge from June 25 to July 2 under the presidency of Sir Lionel Whitby, regius professor of physic in the university. The scientific work will be divided into nineteen sections, which will meet on the three days, June 30 - July 2. The sections, with their presidents, are as follows: medicine, Dr. L.B. Cole; surgery, Mr. Vernon Penn Pennell; obstetrics and gynecology, Mr. J.R. Campbell Canney; anethetics, Dr. Z. Mennell; child health, Sir Leonard Parsons; diseases of the chest, Dr. R.R. Traill; occupational health, Dr. Donald Stewart; ophthalmology, Mr. O. Gayer Morgan; orthopedics, Professor T.P. McMurray; pathology and bacteriology, Professor H.R. Dean; physiology including biochemistry, Professor A.C. Chibnall, F.R.S.; preventive medicine, Dr. G.F. Buchan; radiology, Dr. S.C. Shanks; anatomy and anthropology, Professor H.A. Harris; dermatology, Dr. C.H. Whittle; neurology and psychiatry, Professor E.D. Adrian; nutrition, Professor R.A. McCance; otorhinolaryngology, Mr. V. E. Negus, and pharmacology, Professor E. B. Verney, F.R.S.

The following are among the subjects chosen for discussion: thiouracil in the treatment of thyrotoxicosis ; the modern management of macrocytic anemias; surgery in hypertension; tuberculous adenitis; cancer of the breast; the problem of infertility and its treatment; analgesia in midwifery; management of the third stage of labor and its complications; anesthesia for thoracic surgery; neonatal mortality; malignant disease in infancy and childhood; bronchial carcinoma; relation between upper respiratory infection and radiologic infection and radiologic appearances of the lungs; surgery of congenital heart disease; the present treatment of pneumonia; human relations in industry; aviation medicine; ophthalmic problems associated with gynecologic and obstetric conditions; the significance and interpretation of refraction; contact lenses; the heredity of eye diseases; nutritional eye diseases; clinical significance and treatment of lesions of the intervertebral disk; the operative treatment of fractures; injection treatment of osteoarthritis; advances in our knowledge of the Rhesus factor; acute and subacute hepatitis; recent work on proteins and its medical applications; plasma and blood derivatives in the treatment of burns; occupational dermatitis; investigation and treatment of epilepsy of late onset; early recognition and management of senile degeneration, affections of the sphenoid sinus and their treatment; antihistaminic substances, and agents determining and influencing the functions of the pars nervosa of the pituitary.

New Health Regulations for Air Travel

New measures to reduce the risk of aircraft or travellers by air bringing into this country disease from abroad have come into force on April 1. The speed of air travel has produced special medical problems. For instance, while a journey from India to London by sea normally takes three weeks, during which any infectious illness on board would become known and could be dealt with at the port of arrival, a passenger by air can fly from Singapore in two days and from India or South Africa in thirty-six hours. This time is much shorter than the normal incubation period of plague, cholera, yellow fever, typhus and smallpox — the diseases with which international control is mainly concerned.

An International Sanitary Convention on air travel was drawn up in 1933 and extended in 1944 to standardize the measures which may be taken for the control of infectious diseases when an aircraft passes from one territory to another. The first public health regulations for aircraft in this country came into force in 1938; with the nationalization of airfields and the changing conditions of air travel, they have now been replaced by new regulations. All incoming aircraft from places abroad will be met by medical officers. On arrival the commander of the aircraft will give the names of the places in which it has been during the last fourteen days. Passengers showing no symptoms of an infectious disease will be given a card setting out the simple precautions to observe if they fall ill within twenty-one days of arrival. These include showing the card to their physician, who thus learns that his patient has recently arrived from abroad, where he may have been exposed to infection. If there is any doubt about the nature of the illness, the physician is to inform the health officer of the area at once. Thus all cases of illness in travellers arriving by air from abroad can be traced and the health authorities can take the necessary precautions, including isolation of the sick and the supervision of contacts. The regulations also apply to aircraft which, because of emergency or other reason, alight outside a customs airport.

Dentists Reject Work Under Health Service Act

The representative board of the British Dental Association has adopted a resolution recommending that dentists refuse to enter service under the National Health Service Act until it is so amended as to include the principles advocated by the association. The resolution, which was adopted by 85 votes to 4, recorded that the board considered the proposals to be not in accord with the principles essential for a satisfactory dental service for the nation. The provisions of the act would curtail the dentist's clinical freedom to the detriment of the standard of treatment. The method of remuneration on which the Minister insists, payment of a fixed sum for each item of treatment, irrespective of any special skill employed or the amount of time involved, would put a premium on hurried and shoddy work.

Suffocation Of Infants By Milk Feeds

From time to time cases are reported from the coroners' courts of infants suffocated by inhalation of vomited milk feeds. This accident is particularly liable to occur in weakly infants, those mentally defective and those suffering from malformations such as cleft palate. In consequence of an editorial on the subject published in the Lancet, C.J. Polson and D.E. Price, of the department of forensic medicine of the University of Leeds, have published (*Lancet* 1:343 Feb 28, 1948) an analysis of recent cases coming under the jurisdiction of the Leeds coroner's court. In the years 1945-1947, 21 infants aged 9 months or less died of inhalation of vomit. The annual incidence in these three years was 6 per cent, 9 per cent and 15 per cent, respectively, of all deaths of infants, excluding stillbirths, examined in the city mortuary in these years. The depositions suggested that the same cause was responsible for the deaths of at least another 10 infants, in whom the cause of asphyxia was not ascertained or was reported to be some other factor such as convulsions. Soft feather pillows were held to be responsible for 2 deaths and probably responsible for another 4. In 1 case a shawl was believed responsible for preventing the free escape of vomit and so predisposing to its inhalation. Some of the infants were described as "windy," or prone to retch or vomit after feeds, while lying down, and it was a common practice to allow infants to suckle at the bottle when laid in their perambulators or cots. The stomach contents, several hours after the last feed, were distinctly in excess of what was ordinarily to be expected. The kind of food was recorded in 16 cases. Of these, 9 had national dried milk, 4 had "ostermilk," while 3 (of which 1 had a supplementary feed of cows' milk and water) were breast fed. One observer, Gardner, has recorded a predominance of artificially fed infants among his cases. The lesson drawn from these cases is that the preparation of artificial milk foods must be carefully performed if lumps are to be avoided. Lumps in the feed may be ingested by the infant if the nipple on the bottle is worn or its opening deliberately enlarged. But there is no information that the ingestion of lumps is in any way injurious or productive of vomiting.

BRAZIL

Rio de Janiero, March 5, 1948.

Tuberculin and Roentgenologic Observation in BCG Vaccinated Children

Dr. Carlos M. Valente, of the Rio de Janeiro City Health Department, published a report on 1,288 children from 12 months to 16 years of age, subjected to the Mantoux tuberculin test and roentgenographic examination. Of these children, all living in a presumably tuberculous environment, 668 had been orally vaccinated with BCG at birth and 620 had not been immunized. Most of them belonged to the poorest classes of the population. According to the tuberculin tests, a decided prevalence of weak specific hypersensitivity could be disclosed in the immunized children. Among the 620 nonvaccinated children a much higher degree of sensitivity to tuberculin was disclosed. On roentgenographic examination of the 620 children, 1.8 per cent manifested residual tuberculosis, 0.6 per cent were suspected of infection and 1.2 per cent had active forms, 5 of the children with bacteriologic evidence of tubercle bacilli. The author concludes that since a definite protection was evidenced in the BCG-vaccinated children in tuberculous environments it is advisable to expand the practice of BCG immunization as a means of fighting the high incidence of the disease in the city.

Rheumatoid Arthritis and the Heart

The problem of rheumatic and rheumatoid arthritis and its relation to the heart is being studied in Brazil, where rheumatism is not such an important etiologic factor of cardiac diseases as in colder climates. Dr. Oswaldo Lucchesi recently published an analysis of 50 cases. The group included 13 men and 37 women, the former varying between 22 and 66 years of age and the latter between 22 and 65 years of age. The duration of the disease in the whole group varied from one month to forty-one years. The clinical examination showed abnormal heart sounds in 24 patients, but in none of them did the abnormalities present any likeness to the rheumatic type. The radiographic examination disclosed 20 patients with enlargement of the heart due to hypertension. The electrocardiograms were normal in 37 patients, the remaining 13 patients exhibiting abnormalities of nonrheumatic type. Of the 14 patients with rheumatic subcutaneous nodules, 7 showed normal clinical signs, heart size and electrocardiograms. In 7 others Dr. Lucchesi reported the observation of an enlarged left ventricle due to hypertension, causing left axis deviation in 4 cases. He concludes that his observations emphasize the difference between real rheumatic fever and rheumatoid arthritis.

Sickle Cell Disease

Dr. Edgard Boturao, of the Misericordia Hospital of Santos, state of São Paulo, published a report on the hematologic study of 358 patients, including about 20 with sickle cell disease. Of the 358 patients, 64 were white, 132 mulatto and 162 Negro, with the percentage of incidence of sickle cells zero, 4.5 and 8.6, respectively. These results show that the incidence of the disease increases in direct ratio to the intensity of pigment. Dr. Boturao points out the importance of the problem at Misericordia Hospital, where 1,946, or 27.5 per cent, of the 7,078 patients admitted during the last nine months were Negroes.

Thymol Turbidity Test in Experimental Poisoning

Dr. Gilberto G. Villela, of the Oswaldo Cruz Institute, tried to ascertain the value of Maclagan's thymol turbidity test in experimental poisoning with carbon tetrachloride, chloroform, sulfanilamide and "dicumarol." Using the technic recommended bv Shank and Hoagland, he performed the tests with the serums of 24 rabbits and 18 rats. The normal values were tested with the serums of 10 rats and 8 rabbits. Since the normal blood of these animals manifested with the thymol reagent only slight turbidity (less than 0.2 unit), larger amounts of the reagent were used (0.2 to 0.4 cc. and 5 cc. Only 20 to 30 per cent of the poisoned animals showed positive reactions (around 2 units). The test was performed with blood collected during and after the poisoning (from two to fourteen days). Notwithstanding, appreciable changes were not observed. For controls, the reaction was tried on 47 normal human serums and on serums from patients with hepatic diseases. Normal serums had turbidity values below 4 units. Dr. Villela concluded that the thymol test is unable to detect hepatic damage produced by drugs like sulfanilamide, chloroform, carbon tetrachloride and "dicumarol." He also suggested that the disturbances in the serum beta-globulin responsible for the positive thymol test appearing in infectious hepatatis and in cirrhosis of the liver are probably not produced by the hepatotoxic agents.

Correspondence

EPILEPTIC PERSONS ARE UNSAFE DRIVERS

To the Editor: --There is a California law which requires that epilepsy, interpreted as " lapses of consciousness which may become chronic," be reported by the attending physician to the state board of health. In this way the epileptic driver is discovered and the use of a license is revoked. A similar law exists in the states of Oregon, Wisconsin and Indiana. The hospital of the University of California has in its files records of many dramatic instances of accidents caused by epileptic persons who have experienced seizures while driving automobiles. It is my impression that if a similar law is enacted in other states, it will mean a substantial contribution toward the prevention of motor vehicle accidents. Dr. W. E. Carter, director of the outpatient department, will provide further information on this subject. Likewise, Mr. Fred Williams, Motor Vehicle Department, Sacramento, Calif. has listed casualties known to have occurred while epileptic persons were driving .

R. WARTENBERG, M.D.
San Francisco, Calif.

RECENT ADVANCES IN TREATMENT OF PULMONARY DISEASE

To the Editor:—In the January 31 issue of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, page 311, the article by James Waring, M.D., on Recent Advances in the Treatment of Pulmonary Disease presents a confusing contradiction of ideas in regard to the therapy of tuberculosis with streptomycin.

In an early paragraph it is stated that "the most experienced men say that they have seen no patient who regretted taking the drug and no patient to whom they regretted giving the drug." Despite this statement, the remainder of the article is filled with warnings against the use of streptomycin. The author also mentions "complete paralysis of both lower extremities with paralysis of bladder and bowels" following intrathecal administration of streptomycin. Dr. Waring further states that some experts "are hopeful that one way or another damage to the vestibular branch of the eighth nerve can be avoided or minimized."

In discussing the future of antibiotic therapy he expresses the hope that a new and safer antibiotic will be discovered. Finally, he states that "the drug is toxic and the immediate and remote bad effects are not accurately predictable", and further mentions that the development of bacterial resistance may leave the patient with an incompletely eradicated infection. I feel that if these are effects of streptomycin therapy there certainly must be both physicians who have regretted giving and patients who have regretted receiving the drug.

RICHARD E. WINTER, M.D.,
New York.

The Letter of Dr. Winter was referred to Dr. Waring, who replies:

The statement about the gratifying experience of "the most experienced men" is correct but my critic fails to appreciate the significance and the emphasis on the phrase "the most experienced men." Perhaps these men were overoptimistic, I am not sure! At any rate, even though experience with streptomycin was admittedly limited and more time was sorely needed for adequate appraisal of its possible good effects as well as its possible bad effects, five things seemed clear as of June 1947: 1. Streptomycin had a remarkable restraining influence on the growth of the tubercle bacillus in culture. 2. It had an astonishingly beneficial influence on tuberculosis in the experimental animal. 3. It had apparently a remarkably beneficial effect on the acute exudative lesions of tuberculosis infection in man. 4. In dosage then prevailing, it frequently damaged the vestibular nerve. 5. After some weeks of its use against human tuberculosis, the organism responsible for the disease frequently showed greatly increased resistance to the antibiotic.

Since June 1947, further experience with streptomycin indicates that a dose of 1 Gm. daily for seven to nine weeks will only rarely cause damage to the vestibular nerve, a confirmation of the hope expressed in my paper. Also, this damage is not serious and is usually well compensated.

We need to know much more about "bacterial resistance." Opinion differs as to its importance, but I am fearful that unless modification of the drug itself or, less likely, modification of dosage schedule can prevent the development of bacterial resistance, the use of streptomycin in human tuberculosis may be greatly limited. This matter of bacterial resistance is disturbing not merely because the organism is no longer inhibited by the drug but for other reasons. If streptomycin is used, sputum converted from positive to negative and a good arrest apparently secured but relapse occurs at the end of one to two years, with a "bacterial resistant" organism now present in the sputum, is cure by nonantibiotic methods now more difficult? In other words, is the patient now worse off than if he had never taken streptomycin? If streptomycin is used with prompt apparent benefit without sputum conversion and without apparent arrest and in a few months a bacterial resistant organism appears in the sputum, is cure by nonantibiotic methods more difficult? Is the patient worse off than if streptomycin had not been used? When bacterial resistance appears, the disease may coincidentally get out of hand! When bacterial resistance appears, is the resistance of the patient to spread of the disease also considerably reduced? We need answers to these questions, which will be answered with time and more experience. Meantime, I reiterate all the warnings in my communication.

I suggest that my correspondent follow the injunctions in my answer to the question " home treatment." In conclusion, let me say that I never wrote anything yet that I could not improve by rewriting.

JAMES WARING, M.D.,
Denver.

Miscellany

TUMOR REGISTRIES

A tumor registry functions as a unit where all cases of certain kinds of tumor may be completely reported, including the history of the patient, roentgenograms of the area involved, stained slides of the tissue examined, a complete report of the diagnosis, and follow-up of the treatment. The first tumor registry was founded by Dr. Emory A. Codman of Boston and embraced the field of bone sarcoma. Dr. Codman soon discovered that conducting a registry was too big a task for one man, so he turned the idea over to the American College of Surgeons, which formally founded a Registry of Bone Sarcoma in 1921. This registry has been in continuous operation at the home of the American College of Surgeons in Chicago ever since, and now more than 3,000 cases of bone sarcoma are registered there. A year after the founding of this registry, the American Academy of Ophthalmology and Otolaryngology contacted the Army Medical Museum, which housed the Army Institute of Pathology, and at their suggestion the Registry of Ophthalmic Pathology was established. This was the first registry instituted by this group, which since then has become known as the American Registry of Pathology, and which now includes a total of fifteen registries. The American Registry of Pathology functions along with the Army Medical Museum as a unit of the Army Institute of Pathology in Washington, D. C.

The other fourteen registries located in the American Registry of Pathology, with the year in which they were established and the sponsor are as follows: the Registry of Otolaryngological Pathology, 1935, American Academy of Ophthalmology and Otolaryngology; the Bladder Tumor Registry, 1927, the Kidney Tumor Registry, 1940, and the Prostatic Tumor Registry, 1943, all sponsored by the American Urological Association; the Lymphatic Tumor Registry, 1925, the American Association of Pathologists and Bacteriologists, the Registry of Dermal Pathology, 1938, the American Academy of Dermatology and Syphilogy; the General Tumor Registry, 1937, the American Society of Clinical Pathologists; the Chest Tumor Registry, 1942, the American Society of Thoracic Surgeons; the Registry of Neuropathology, 1943, the American Association of Neuropathologists; the Registry of Orthopedic Pathology, 1943, the American Academy of Orthopedic Surgeons; the Registry of Gerontology, 1945, the Society for the Study of the Aged; the Registry of Radiologic Pathology, 1947, the American College of Radiology, the American Roentgen Ray Society and the Radiological Society of North America; two special registries, the Registry of Dental and Oral Pathology, 1933, the American Dental Association, and the Registry of Veterinary Pathology, 1944, the American Veterinary Medical Association. The fifteen registries located in the American Registry of Pathology provide an extraordinary accumulation of data on cancer cases, since practically every one of the registries deal with tumor tissue. Pathologic material and related clinical, laboratory, roentgenologic and other data are collected and organized so that the cases can be properly processed and made available for study and research. As living patients are followed periodically, eventually there will be a significant number of life histories of any particular condition to form a basis for definitive studies. The National Research Council, Division of Medical Sciences, has appointed a Committee on the American Registry of Pathology, which serves as an advisor in general administrative, fiscal and professional matters and passes on applications for new registries, submitting recommendations to the Surgeon General of the Army. The Committee is composed of outstanding representatives in the larger specialties. Other registries which are conducted include the Brain Tumor Registry, which is better known as the Cushing Collection at Yale University Medical School, first started by the late Dr. Howard B. Cushing. Dr. Harold Dargeon, director of the Children's Clinic at Memorial Hospital in New York City, has started a Children's Tumor Registry, and records of many unique cancers which affect younger persons are being collected there. The Children's Tumor Registry was formed one year ago for the purpose of collating data with regard to malignant tumors in children and providing a service of consultation. Material will be provided which is based on these two points and is of educational value to professional and lay groups.

Many states are organizing registries for all cases of tumor and cancer. Six states already have well organized units, and these are all part of the diagnostic pattern from which the unique cases reach the national registries. Many state divisions of the American Cancer Society are assisting in the establishment of these registries. The American Cancer Society makes a yearly grant through the National Research Council to the overhead operation of the American Registry of Pathology. The tumor registries are an important link in the overall problem of cancer: early and accurate diagnosis—followed by prompt and adequate treatment (*Cancer News*, January 1948).

Medical Motion Pictures

FILM REVIEW

Know Your Baby. 16 mm., color, sound, 400 feet (one reel), showing time ten minutes. Produced by Crawley Films, Ottawa, in cooperation with the Canadian Committee on Children for the National Film Board of Canada. Procurable on rental or purchase from the National Film Board of Canada, 400 West Madison Street, Chicago 6, and 620 Fifth Avenue, New York 20.

This is a clearly conceived and well constructed film designed to depict the ideal care of a child during the first few months of its life. In logical continuity the film illustrates the proper feeding, bathing and handling of the infant; at the same time it stresses the essential emotional relationship to be cultivated among the child, its mother and its siblings. (Inexplicably, the role of the father is omitted.) Despite minor defects the visual sequences are cogent, interesting and skilfully edited. The vocal commentaries are likewise clear and pertinent. Nevertheless, the film might advantageously be issued in a silent version appropriately subtitled so that it could be more widely shown to expectant parents and others in places where sound projectors are not readily available. The film can be highly recommended for the lay and professional instruction of all who are concerned with psychobiologic welfare of the future adult in his tenderest months of life.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Employee's Refusal to Undergo Spinal Puncture.—The petitioner filed a claim for compensation for a spinal injury received during the course of his employment and, from a judgment in favor of the employer, appealed to the Supreme Court of Tennessee.

The petitioner alleged that he cannot walk in the dark, that he staggers when he does walk, and that he has violent pains in the back and stomach with occasional vomiting. His pupils are contracted "and reacted to light but not to accommodation.". Expert testimony was to the effect that these symptoms strongly indicate syphilis in the tertiary stage, at which stage this disease can be verified only by an examination of 3 or 4 cc. spinal fluid. The only way to obtain this specimen is by injecting a needle into the soft tissue and between the vertebrae, the total penetration being usually from 3 to 5 inches (7.62 to 12.7 cm.) A local anesthetic applied to the cutaneous surface eliminates the only possible pain. There is no bleeding and no infection results, but the patient is hospitalized for a few hours after the puncture to prevent headache. This means of procuring a specimen of spinal fluid has been employed by medical science for many years, and there is no record of resulting death, injuries or fainting. If the puncture is performed in an unskilled manner, paralysis lasting to a maximum of four hours may result. The physician proposed by the employer to perform the examination was an expert of recognized standing, and the employer proposed to pay all expenses. The petitioner refused to permit any physician to extract this fluid because he was afraid it might result in death or permanent injury, although he offered no evidence of any possibility of such results other than to say that he once heard that a distant kinsman was injured permanently in this manner.

The Tennessee workmen's compensation law provides that: "The injured employee must submit himself to the examination by the employer's physician at all reasonable times if requested to do so by the employer.... If the injured employee refuses to comply with any reasonable request for examination...his right to compensation shall be suspended and no compensation shall be due and payable while he continues such refusal."

It is generally held, said the supreme court, in construing this law that a reasonably made request by an employer for a surgical operation which is not attended with extraordinary pain or suffering or danger to life or health and which offers appreciable prospect for relief is a reasonable request which the employee must either grant or release the employer from further obligation, at least as long as he refuses. By appropriate analogy, the supreme court continued, and what seems to us to be sound principle, we hold that when it reasonably appears that the affliction of the employee may be due to some cause not arising out of and in the course of employment, then a request for such necessary examination as will determine whether the illness is due to such cause is not unreasonable, if it satisfactorily appears without contradiction that the conducting of such an examination is not attended with appreciable pain or suffering or danger to life or health. In the case at bar, said the court, it reasonably appears that plaintiff in error may be suffering from syphilis in the tertiary stage. The only way known to medical science to certainly determine whether he is suffering from such syphilis is to examine a specimen of his spinal fluid. The obtaining of that specimen requires the doing of an act to his body which is not attended with appreciable pain, suffering or danger to life or health. The examination falls within the same class as that which requires a specimen of blood. The examination requested, the supreme court concluded, is in our opinion entirely reasonable, and the refusal of the employee to submit thereto is arbitrary and without justification. Accordingly the judgment against the plaintiff was affirmed.—Trent v. American Service Co., 206 S. W. (2d) 301 (Tenn.,1947).

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: Oral. New York, April 12-15, Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York 22..

American Board of Internal Medicine: Written. Oct. 18. Final date for filing application is June 1. Asst. Sec-Treas., Dr. W.A. Werrell, 1 West Main St., Madison 3, Wis.

American Board of Ophthalmology: Oral. Baltimore, May 20. Chicago, Oct. 6, Written. Various centers. Jan. 1949. Final date for filing application is July 1, 1948. Sec., Dr. S. Judd Beach, 56 Ivie Rd., Cape Cottage, Maine.

American Board of Orthopaedic Surgery: Part II. Chicago, January 1949. Final date for filing application is August 15, Sec., Dr. Francis M. McKeever, 1136 W. 6th St., Los Angeles 14.

June 15-19. Sec., D.M. Lierle, University Hospital, Iowa City.

American Board of Pediatrics: Oral. Cleveland, April 23-25. Chicago, June 25-27. Seattle, Sept. 10-12. Atlantic City, Nov. 17-19. Written. July 30. Sec., Miss Lea Leonard, 718 Royal Union Bldg., Des Moines, Iowa.

American Board of Physical Medicine: Parts I & II. Chicago, June 19-20. Final date for filing application is April 17. Sec., Dr. R.L. Bennett, 30 N. Michigan Ave., Chicago 2.

American Board of Plastic Surgery: Examinations are given in April and November of each yesr in the home town of applicants. Sec., Dr. Robert H. Ivy, 1930 Chestnut St., Philadelphia.

American Board of Psychiatry and Neurology: Oral. All Groups, San Francisco, October. Final date for filing application is July 15. Sec., Dr. F. J. Braceland, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Surgery: Written. Part I. Oct. Final date for filing application is July 1. Sec., Dr. J. S. Rodman, 225 S. 15th St., Philadelphia.

American Board of Urology: Chicago, Feb. 12-16, 1949, Sec., Dr. Harry Culver, Route #13, Sunnyside Rd., Minneapolis 4.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

Case of Shigella Alkalescens Cystopyelitis and Bacteremia. L. Cardon and O. Felsenfeld.—p. 55.

Intestinal Coccidiosis: Report of 2 cases of Isospora Hominis. J D. Kirshbaum.—p. 58.

Elevated Serum Amylase in Alcoholic Addicts.—Domzalski and Wedge cite literature to the effect that alcohol may play a role in the production of pancreatitis (pancreatic necrosis). Both patients with chronic pancreatitis recently observed at their hospital were chronic alcoholic addicts. The authors made amylase determinations on the serums of 50 alcoholic persons and of 50 nonalcoholic control patients. Elevated serum amylase was found in 12 of 50 chronic alcoholic addicts following recent alcoholic intoxication but in only 1 of 50 control patients. It is suggested that elevation of serum amylase in those with alcoholism represents evidence of subclinical pancreatitis and that this condition may be a precursor of severer clinical forms of pancreatitis.

Termination of Therapeutic Malaria with Chloroquine. R. R. Kierland and W. G. McCreight.—p. 57.

Penicillin Alone in Neurosyphilis.—The report by Stokes and his co-workers is the fourth in a series presented by the University of Pennsylvania on the treatment of neurosyphilis with penicillin alone. Since the organization of the Pennsylvania group, 1,004 patients have been treated with penicillin, of whom 422 had neurosyphilis. There are no striking differences between the effect of earlier lower and later higher dosage, nor is great additional effect secured by second and third courses. The good effect of penicillin ranges through all the categories of neurosyphilis from asymptomatic neurosyphilis to paresis. A comparison of penicillin with malaria treatment in neurosyphilis (based on the literature) indicates that in paresis penicillin "catches up" on malaria by the third year, equaling it in symptomatic improvement and producing a superior effect on the spinal fluid. In taboparesis and meningovascular neurosyphilis the results with penicillin are serologically superior and clinically equal to those with malaria. In tabes dorsalis the clinical improvement is one-third better than with malaria in the second and third years, and spinal fluid normality is obtained twice as often with penicillin as with malaria in the same period. In asymptomatic neurosyphilis the results obtained with penicillin are the best in any diagnostic category. Of 65 patients with lightning pains, two thirds showed some improvement. Of 6 patients with gastric crises, 3 showed improvement. The most important complication of penicillin therapy in neurosyphilis is the Herxheimer reaction, or therapeutic shock. Serious damage may be done by full initial dosage. Ten thousand units per injection at the start is not low enough. Five hundred units per injection, ascending to full dosage in four to five days, is being tried. A course of 9.6 million units of water-soluble penicillin on a two hour round the clock schedule covering ten to twenty days, with a full dosage level per injection of 40,000 to 80,000 units, is on trial.

Division of Abdominal Aorta for Embolus.—The case reported by Cooper and his associates concerned a soldier aged 22, who had sustained a penetrating wound of the left arm and chest. Roentgenograms showed a foreign body in the heart. About two months later an attack of severe, sharp, stabbing precordial pain radiating to the abdomen and region of the right hip occurred. In view of the changes in pulsations in the extremities it was believed that the pain had been produced by shifting of the bullet in the aorta or by a dissecting aneurysm of the aorta. During the following nine days the pulse in the right lower extremity varied in amplitude and that in the left was absent. Then the episode of thoracic and abdominal pain recurred. About a week later the patient complained of weakness and fatigability of both legs and coldness of the right foot. Since the patient complained of recurrent attacks of pain in chest and abdomen, it was feared that the abdominal aorta was being eroded by the foreign body. Fluoroscopic examination demonstrated motion of the foreign body, and there was evidence of peripheral vasospasm in the lower extremities from irritation of the aortic wall. An operation was planned. The conditions present gave an ideal sequence leading to ligation of the aorta. The patient was young with the vascular elasticity of youth. Occlusion of the aorta was not sudden but progressive over several weeks, with variations in the completeness of obstruction to blood flow. At the time of operative intervention the vessel had become completely occluded, with an adequate collateral circulation in the legs as manifested by the prompt rise in skin surface temperatures of the toes. Postoperatively, the distal vascular bed was relieved of vasospasm produced by the foreign body. The lower extremities reacted normally to changes in environmental temperature after aortic division.

One Stage Anastomosis of Colon.—Hinton and Localio report observations on 26 consecutive colonic resections in all regions of the colon above the peritoneal reflection, which were done in one stage without a proximal colostomy or ileostomy and were anastomosed aseptically with the aid of a Furniss clamp. There was a single fatality, which occurred on the fifth day while the patient was returning from the lavatory. There were 3 abdominal complications. The postoperative hospital stay varied from seven to seventy-six and averaged nineteen days. Only nonobstructed patients were selected for this procedure. Five to seven days were allowed for preoperative preparation. Attempts were made to replenish the stores of tissue proteins. The patients received, per day, 2,000 cc. of "amigen," 500 mg. of ascorbic acid and 200 mg. of vitamin B complex parenterally. Anemia was corrected by transfusion of whole blood. The patient was placed on a high protein, low residue diet. Purging was carried out with magnesium sulfate. The patient received 12 Gm. of succinylsulfathiazole per day. At operation the colon was found collapsed and free from fecal material. A transfusion of whole blood was administered immediately postoperatively. A Levine tube was left in the stomach, but suction was not used. Fluids were permitted by mouth, excess gastric residue being siphoned off by the Levine tube. Nutrition was maintained by infusion of "amigen" and dextrose in distilled water. When the patient passed gas by rectum, the Levine tube was removed, parenteral feeding was gradually discontinued and oral feeding gradually liberalized. The bowels moved spontaneously between the third and fifth days. All patients were ambulated on the first postoperative day and daily thereafter. They were urged to use the bathroom facilities rather than the bedpan. Succinylsulfathiazole was used postoperatively. The authors consider aseptic anastomosis with the Furniss clamp a satisfactory and simple method.

Penetrating Wounds of Cerebral Ventricles.—The report by Schwartz and Roulhac is based on 50 consecutive cases of verified ventricular penetration. Thirteen of the penetrations were operated on primarily by the authors. Thirty-one wounds were inadequately débrided at forward installations and were reoperated by the authors one or more times because of infection or retained foreign bodies. Fourteen of these had retained bone chips or metallic foreign bodies lying within a ventricle. There were 5 cases of ventricular penetration which were operated on at other installations with recovery. Over-all mortality was 15 cases, of which 9 were due to infection and 6 to vital brain damage. Treatment of ventricular wounds is no different from that of other penetrating wounds of the brain, even though they are more serious. Patients suspected of having a ventricular wound should be given top priority for surgery, for the greater the delay the greater is the risk of infection or clot in the ventricles. The crux of the treatment of these wounds is adequate débridement of the entire tract, including the ventricle, under direct vision. Infected cases should be handled in the same way, with removal of debris, retained bone fragments and pus, and closure of the wound. Direct instillation of penicillin at the time of operation, plus parenteral penicillin and sulfadiazine are effective only when combined with surgical measures.

Lymphogranuloma Venereum: Observations on 388 Patients at Bellevue Hospital. M. J. Costello and C. S. D'Avanzo.—p. 112.

Lymphogranuloma Venereum.—Costello and D'Avanzo report on 388 patients admitted to the dermatologic wards of Bellevue Hospital with a diagnosis of lymphogranuloma venereum in the ten year period 1936 to 1945, inclusive. Of the patients 317 were men. During the last two years there has been a decided increase in the female patients, in whom the disease was more chronic and longer duration. Nearly three fourths of the patients were Negroes, and 3 of the white men admitted sexual relations with Negro women. The authors believe that this fact might be elicited more frequently if this information were definitely sought. The average duration of the disease in patients with inguinal involvement of the lymphatic nodes previous to hospitalization was thirty and seven-tenths days, while the average duration of the disease in patients with rectal changes previous to admission to the hospital was thirty-two and two-tenths months The genitals and the inguinal lymph nodes were primarily involved in 344. In 40 the anorectal region was involved. There were also 2 cases with involvement of the perianal region, 1 of the mandibular region and 1 of the scrotal area. An intradermal test with Frei antigen was performed in 380 of the 388 patients. Of these, 365, or 95.5 per cent, showed a positive reaction. There were 15 patients who had inguinal adenopathy for less than one week and in whom the reaction in the initial Frei test was negative. Reactions in repeated Frei tests at subsequent intervals became positive. The Frei test should be repeated several times in suspected cases of inguinal adenopathy. Before the use of sulfonamide drugs for lymphogranuloma venereum, routine treatment consisted of aspiration of the buboes and the administration of antimony potassium tartrate or stibophen. Since 1938 the sulfonamide drugs have been used, and these together with rest in bed now constitute the best treatment. Surgical intervention in the cases of early disease should be reduced to a minimum. In all cases of "inguinal abscess" and perianal infection and abscess there should be an intradermal test with Frei antigen before operative intervention is performed.

Syphilis: Review of Recent Literature. F. W. Reynolds and J. E. Moore.—p. 799.

Bleeding Peptic Ulcer.—Meulengracht treated 1,031 patients with bleeding peptic ulcer by free feeding as a routine measure during the period June 1931 to June 1946. Death occurred in 26 patients, 17 men and 9 women, during their stay in the hospital. All except 1 of these patients were over 40 years of age and half were over 60. Many had large ulcers penetrating into the pancreas or the liver, and many had complicating diseases. If all the fatal cases are included, the gross mortality is 2.5 per cent. If cases are excluded in which death was entirely or principally due to causes other than bleeding as well as those in which the patients died twenty-four hours after admission to the hospital and therefore before they had received the treatment, the net mortality is 1.5 per cent. The risk of hemorrhage in the free feeding program is greatest in the higher age groups, presumably because of the poor condition of the vessels and the various complicating diseases in those age groups. In all the fatal cases the bleeding manifested itself as hematemesis. The latter indicates a worse prognosis than melena. A more ample use of blood transfusions is recommended in cases which threaten to terminate fatally.

Diabetic Acidosis.—Franks and his co-workers limited the intake of 28 patients with severe diabetic acidosis or coma to water, sodium chloride, dextrose and insulin supplemented in some cases by plasma, blood or alkali. Determinations of the blood sugar content, carbon dioxide combining power, chloride and inorganic phosphorus contents and hematocrit readings were made at approximately four hour intervals for twenty-four hours. Seven patients received no supplementary dextrose until the blood sugar level had fallen within the normal range. Twenty-one patients received dextrose intravenously or by mouth from the onset of therapy; 10 patients were given dextrose at rates of 6 to 20 Gm. per hour during the first period, and dextrose was given at rates exceeding 20 Gm. per hour to 11 patients. The severity of the condition on the patient's admission to the hospital was taken as a basis for the evaluation of therapeutic results. The patients of the saline group had an average severity index of 24 per cent and an actual fatality rate of 14 per cent, while the 11 patients receiving large amounts of dextrose early had a severity index of 37 per cent and an actual fatality rate of 36 per cent. The administration of dextrose in the early hours resulted in prolonged hyperglycemia, pronounced glycosuria and polyuria. The maintenance of hyperglycemia did not accelerate the disappearance of acetone from the urine or the rise in plasma carbondioxide combining power. The early administration of dextrose appeared to have an unfavorable influence on the outcome in the group as a whole. For further evidence the clinical analysis was extended to a total of 71 patients with diabetic coma. Sixteen of these received sodium phosphate and will be considered in another paper. For 22 of the remaining, from whom dextrose was withheld for at least the first four hours, the mean severity index was 40 per cent and the actual fatality rate was 36 per cent. The other 33 patients received dextrose during the first four hours and had a mean severity index of 37 per cent but a fatality rate of 52 per cent. These results indicate that dextrose should not be administered in diabetic acidosis until the blood sugar level has fallen within or near normal range.

Rheumatoid Arthritis in Children.—Pickard reports the end results in 35 cases of rheumatoid arthritis in children who had been followed for thre to more than five years. Etiologic factors in these cases appear to have been infection, trauma and allergy. The essential feature of the disease is an altered specific reaction of the patient to these activating agents. There is essential agreement with the conclusion of Colver that the disease is self limited. There is essential disagreement with the same author in regard to the "second attack" or recrudescence after quiescence. After the involvement of various joints by the rheumatoid process, a wide difference in the outcome may be anticipated according to the joint involved, with poorest results in the elbows, the carpal joints and the wrists and relatively good in the ankles and the knees. Visceral lesions accompany the severe forms of the disease; "rheumatism-like" lesions in the heart and amyloid degeneration in the liver and spleen are of greatest importance. A persisting monarticular form of rheumatoid arthritis in children may be observed at times and is difficult to distinguish in some cases from tuberculous synovitis. Rheumatoid arthritis and rheumatic fever may closely resemble one another. There is a reasonably good basis for the removal of focal infection during the active phase of the disease. Surgical attack on joints during the active phase of the disease does not seem advisable. The incidence of recovery is high if all cases are taken into consideration; 3 patients died, 11 were left with residual crippling of various degree and 14 recovered without residual crippling. In 7 patients the disease was still active at the time of last observation.

Panarteritis in Allergic Persons.—Miale, Doege and Piehl report the occurrence of acute necrotizing arteritis in 2 men, aged 40 and 67, respectively, who both had definite atopy. The first patient had gangrene of the ileum with acute allergic dermatitis on the basis of an acute arteritis. The evidence of acute renal damage coincident with the abdominal condition, plus the residual renal damage demonstrated by a phenolsulfonphthalein test of renal function suggested that there was simultaneous arterial involvement in the kidneys and possibly in other organs. The condition was diagnosed early in the course of the illness, all medication stopped and a good recovery made. The second patient died, and final diagnosis on necropsy was visceral angiitis (panarteritis), glomerulonephritis on the basis of visceral angiitis, pleural adhesions, hydrothorax, ascites, fibrous obliterated pericarditis and passive congestion of the lungs, spleen and liver. The vascular necrosis was severest in the kidneys and liver. Previous to the fatal disease the patient had been seen many times in the dermatologic department because of severe asthma and allergic dermatitis. In these 2 cases there is enough evidence to show that the relationship between hypersensitivity and acute arterial disease is more than accidental. In case 1 all medication was stopped as soon as the diagnosis was made in the hope that the antigen might be excluded by such means. This may be a lifesaving measure when the antigen is exogenous. The authors feel confident that more and more cases will be recognized before autopsy is performed. New developments in the field of the antiallergic drugs may lead to a more active method of therapy in the near future.

*Poliomyelitis: Study of Epidemic of 40 cases in Key West, Fla. May-August 1946. W. D. Davis and C. M. Silverstein.—p. 740.

Electrocardiographic Changes in Electric Convulsions.—Altschule and his associates made electrocardiographic studies on 10 patients, who were treated with electrically induced convulsions. Five patients were studied onceor twice and the other 5 were studied four to seven times each. Observations made on these patients corroborate the previously recorded shifting of the site of origin of the heart beat, as evidenced by pronounced sinus arrhythmia, periods of sinus bradycardia, frequent auricular and nodal premature beats and, in 1 instance, auricular tachycardia. This type of disturbance in cardiac rhythm is a consequence of vagal hyperactivity. The increase in vagal activity usually does not induce sufficient cardiac inhibitation to cause more than transitory bradycardia; the systemic circulation is not slowed; the occurrence of vagal arrhythmia goes with other evidences of antonomic stimulation exhibited by patients during and after convulsive seizures.

Poliomyelitis in Key West.—Davis and Silverstein report observations they made in the course of an epidemic of poliomyelitis which began on the island of Key West in May 1946. The population of Key West at the time of the epidemic was about 14,000 civilians and about 3,500 naval personnel and their families. There were 40 verified cases of poliomyelitis and 190 cases of suspected and probable abortive poliomyelitis. There were 7 pregnant women with poliomyelitis; 6 of them had the paralytic form. Nearly three fourths of the patients in Navy families were adults (19 to 33 years of age), whereas only 10.5 per cent of the civilian patients were adults. There were three instances in which 2 verified cases occurred in the same family (6 patients). Thirteen of the remaining 34 patients gave a history of a febrile illness resembling poliomyelitis in one or more of the family at the same time. Eight patients had a normal temperature on admission. Since fever is usually a cardinal sign of infection, a patient suspected of having poliomyelitis who has no fever, but mild symptoms, should be asked routinely about recent fever or should be watched for the subsequent development of fever. A history of direct contact with persons known to have poliomyelitis was obtained for 18 (almost one-half) of the patients. Polluted beach water and flies were also possibly incriminated in the transmission of the virus. The treatment was that followed by the Georgia Warm Springs Foundation with regard to general nursing care, use of hot packs, baths and passive motion, reeducation of muscles and prolonged observation and treatment after the acute stage of the disease.

Bronchogenic Carcinoma.—Gagnon says that from 1934 to 1945, inclusive, 508 patients with bronchogenic carcinoma were admitted to the Toronto General Hospital. He excludes from consideration 284 patients in whom the diagnosis appeared obvious from clinical examination or after biopsy from secondarily involved glands or skin. In the 224 patients forming the basis of this review, the diagnosis was determined by microscopic examination of tumor tissue obtained either by bronchoscopy, thoracotomy biopsy or necropsy. The increase is apparent and can probably be explained by increasing awareness on the part of physicians, which leads to a more frequent recognition. The disease is much commoner in the male, there being only 25 females in this series. The oldest patient was 84 and the youngest, 15. The majority of patients were between the fourth and sixth decades of life. Bronchoscopy permitted a positive diagnosis in 69.1 per cent of those examined by this means. The disease is somewhat more frequent on the right side than on the left side. Eighty-six chests were opened and resection was completed in 49 cases, 5 of which were lobectomies. Operative mortality for lobectomy is nil; the maximum survival was nine months. Operative mortality following pneumonectomy in the series was 36 per cent, though for the last year of the review it was only 25 per cent. In 1946 the mortality was further reduced to 6.6 per cent. One fourth of all patients on whom pneumonectomies were performed are alive today and apparently free of disease, their survival ranging from seven months to eight and one half years.

Cervical Herniation of Lung.—Meakins and associates state that herniation of the lung is rare, only 200 cases having been recorded in medical literature. The authors differentiate between cervical, thoracic and diaphragmatic hernia. They quote Maurer and Blades as saying that "cervical hernias usually occur through the superior aperture of the thorax in the interval between the sternocleidomastoid and scalenus anticus muscles following some tear or deficiency in Sibson's fascia which normally limits the cervical excision of the dome of the pleura." The authors report 2 cases of cervical hernias of the right lung. First, a man aged 58 had a multiplicity of lesions, including carcinoma of stomach and duodenum. Necropsy confirmed these lesions as well as herniation of the apex of the right lung. The herniation could have been due to a congenital structural defect in the apical and cervical area. In view of the clearcut history of injury to the affected area with the immediate appearance of the bulge one can assume that in this case trauma was probably the originating factor. Injury could have been superimposed on congenital weakness. The second case concerned a man aged 53. In this case there was strong evidence that trauma was the etiologic factor.

*Use of Radium in Nasopharynx for Deafness and Its Clinical Effects: Report of Cases. J. L. Jennings.—p. 24.

Use of Radium in Nasopharynx.—Jennings used radium in the nasopharynx by means of a nasal applicator which was designed by Drs. Crowe and Burnam. A capsule of "monel" metal containing 50 mg. of radium sulfate measures 15 mm. in length, has an inside diameter of 1.7 mm. and a wall 0.3 mm. thick. This allows the beta rays to penetrate 3 mm. of tissue. Indications for the use of radium in the nasopharynx are: blockage of the eustachian tube by lymphoid tissue; the presence of lymphoid tissue in the nasopharynx in conjunction with nasal allergy, postnasal discharge, frequent colds and aero-otitis, and also a small area of lymphoid tissue in the nasopharynx which harbors infection and sensitizes the patient. The radium applicator is allowed to stay in place for twelve minutes and then is transferred to the opposite side of the nose for the same period of time. The treatment is carried out at two to three weeks' intervals for three to four applications of radium. At times it is wise to remove the large mass of adenoids surgically before radium therapy. This eradicates the small remnants of adenoid tissue possibly not removed at the surgical procedure. With this method it is possible to eliminate in six months the lymphoid tissue which may require ten to twelve years for removal by natural atrophy. The author cites encouraging results obtained with radium in asthma and allergic conditions and in earache without discharge, but he admits that not all patients are relieved or improved.

Poliomyelitis Virus in Familial Associates.—Brown and his collaborators in order to ascertain the role of the familial associate as a healthy carrier or a possible source of infection of poliomyelitis made studies on four families. Two criteria were required: first, that the family include at least two children other than the one with poliomyelitis; second, that collection of specimens could be started within three days of onset of illness in a member of the family. The occurrence and duration of the carrier state in familial associates of those with recognized cases of poliomyelitis was studied by the examination for virus of stool specimens collected from the members of the four families at regular intervals for a period of over two months. The results indicate that virus may persist in their stools continuously for four to five weeks; virus may be encountered intermittently in the stools; in some instances virus may be present for brief periods only; children are more likely to maintain virus than are adults in the same family; infection of a family takes place rapidly, suggesting simultaneous infection from a common source.

Further Experience with Range Finding Test in Industrial Toxicology Laboratory. H. F. Smyth Jr. and C. P. Carpenter.—p. 63.

Toxicologic Studies on Alkyldinitrophenols Used in Agriculture.—Spencer and his co-workers say that the dinitrophenols have been used for decades for the control of mites, aphids, scale insects and other pests. During the last ten years 2-cyclohexyl-4,6-dinitrophenol and its compound with dicyclohexylamine have gained wide acceptance as insecticides in greenhouse, field and orchard. Experimental work was undertaken in order to obtain toxicologic information on the hazard associated with the use of the dinitrophenols. Experiments were made on rabbits and guinea pigs. Contact with the dinitrophenols incident to their use in agriculture does not present a significant problem from cutaneous irritation. The infrequent person who is hypersensitive to this class of compounds should not work with these materials. The systemic toxicity of the dinitrophenols is sufficiently high that any one of them may present a health hazard from the inhalation of dusts or sprays. The inhalation of either liquid or dry mix concentrates (greater than 5 per cent) of any of these compounds should be avoided. In some cases respirators may be necessary. Low concentrations of the dinitrophenols are commonly found in preparations ready for field use, but reasonable care should be taken to avoid breathing excessive amounts of the dust or spray. The oral intake of the dinitrophenols should not present a problem. Care should be taken to wash well before eating. No significant health problems have arisen from residues remaining on fruits and vegetables. There is usually ample time for the removal of the residue before harvest by volatilization and by the leaching action of rain.

Determination of Lead in Urine.—Cholak and his associates point out that there has long been a need for a rapid analytic method which can be relied on to separate persons who have been subjected to hazardous lead exposure from those whose exposure to lead has been negligible or within safe limits. Such a screening test, as applied to freshly voided samples of urine, is described in detail. The method has been designed to require a minimum of equipment and manipulation and, once standardized, can easily be carried out by a well trained laboratory technician. The method is offered with the warning that although it is capable of the accurate determination of lead if followed faithfully, it does not distinguish between lead and bismuth, and therefore any results indicative of abnormal absorption of lead must be checked by the use of a more specific and precise method.

Electroencephalographic Changes in Water Intoxication.—Cohn and his co-workers employed the pitressin hydration test in 23 young white men, all in naval service, who were admitted to the hospital for study following one or more attacks of syncope, transitory impairment of consciousness or convulsion. The illness presented by the group was unusual, first, in the relative infrequency of the attacks and second, in the short duration of the disease. The authors observed that water intoxication gave rise to low frequency activity in the electroencephalogram in nearly all the subjects. The bioelectric changes were similar to those produced by insulin-induced hypoglycemia and oxygen poisoning. The authors conclude that the pitressin water test is not a specific test for epilepsy. They think that water intoxication, in common with hypoglycemia and oxygen metabolism collapse, is probably a phenomenon of intraneuronal dysfunction. In certain epileptic persons a positive water balance apparently disturbs already poorly functioning neurones, as determined by the electroencephalographic low frequency activity, and thereby acts as the detonating mechanism for the convulsive discharge. The absence of abnormal cerebral electric activity in water intoxication does not indicate that the observed patient does not have clinical epilepsy. In the types of patients in the study, the pitressin hydration test is of limited value for the diagnosis of epilepsy.

Temporal Arteritis. Critical Review of Proven Cases with Report of Additional Case with Pernicious Anemia. M. Protas and A. G. Saidman.—p. 34.

Penicillin and Streptomycin in Bacterial Endocarditis.—Zeller and his associates treated 42 patients with bacterial endocarditis by means of penicillin and 1 patient with penicillin and streptomycin. Sixteen patients died, 14 from active infection and 2 of heart failure after the infection was apparently cured. Problems concerning the use of penicillin in the treatment of bacterial endocarditis are outlined and discussed. A plan for management of patients with bacterial endocarditis is recommended.

Exfoliative Dermatitis Following Penicillin.—Derzavis and Beinstein report the case of a man, aged 56, who received one intramuscular injection of 300,000 units of penicillin in an oil and beeswax vehicle for treatment of traumatic cellulitis of the right ring finger and regional epitrochlear lymphadenitis. Within six hours he experienced severe generalized itching. On the following day there was an acute erythematous macular and maculopapular eruption over all the extremities and genitalia. During the next four days the eruption progressed through a vesicular stage in these regions followed by the appearance of hemorrhagic vesicles on the legs and thighs and a few scattered hemorrhagic vesicles on the trunk, accompanied by bullous lesions in the intertriginous areas. The peak of the dermatosis was apparently reached between the fifteenth and twentieth days, and gradual subsidence followed during the next fortnight with healing of all lesions and exfoliation of almost the entire skin in extensive keratinous sheaths. There was no reaction when the patient partook freely of peanuts and honey. The mechanism of allergic reaction to penicillin is interesting in this case because of the moderate dermatophytosis present and the severe local reaction in those regions about the toewebs. The authors cite experimental studies by other investigators that suggest the possibility of sensitization to penicillin on the basis of cross sensitization to superficial fungous diseases. Physicians should realize that penicillin is not a reactionless drug.

Anticoagulants in Venous Thrombosis.—According to Evans and Dee "dicumarol" has provided since April 1941 the predominant method of therapy at the Lahey Clinic. In the majority of cases a combination of heparin and "dicumarol" has been used. During the first four years heparin was given by continuous intravenous drip to cover the latent period of "dicumarol." For the past two years deep injections of heparin in Pitkin menstruum have been given subcutaneously. Evans and Dee review results obtained in 184 cases of postoperative venous thrombosis with or without pulmonary embolism during the five years 1942 to 1946. Sixty-three patients received heparin intravenously. Fifty-five received heparin in Pitkin menstruum. One to five injections of heparin in Pitkin menstruum were necessary according to the patient's refractoriness to "dicumarol." To the 184 cases must be added 54 in which patients with postoperative pulmonary embolism died untreated, because such deaths either occurred suddenly or were unrecognized as thrombosis with embolism. This makes a total of 238 cases of thromboembolic disease, or an incidence of 0.42 per cent among approximately 56,000 major surgical operations. There were 6 fatal cases in the series of 184. Two were postoperative chemical deaths. One patient early in the series died of hemorrhage from "dicumarol" poisoning. This leaves 3 fatal cases of thromboembolic disease. These 3 deaths occurred in the particularly dangerous groups of cases in which the patients had already suffered one pulmonary embolism. On analysis, none of these 3 cases presented a clearcut argument against the efficacy of anticoagulation therapy. Since 85 per cent of patients with fatal pulmonary emboli give warning signs, usually a low temperature and tachycardia or a history of previous thromboembolic disease, or have varicose veins, a plea is made for better prophylaxis. This can be accomplished by leg exercises, bandaging of limbs, early ambulation prophylactic ligation in debilitated patients over 60 years of age or the administration of "dicumarol" on the fourth day after operation.

Epidermoid Carcinoma of Bronchus of Right Lower Lobe. Bronchiectasis.—p. 63.

Toxic Effects of Gases and Vapors.—Clinton thinks that many illnesses resulting from the inhalation of toxic gases or vapors are ascribed to other causes, because the syndrome produced may resemble in every particular one of several common organic diseases. The patient is frequently not aware that the air he is breathing contains a noxious agent and fails to associate the breathing of some odd smelling but essentially nonirritating air with the occurrence of illness ten days or two weeks later. The author presents some of the basic principles involved in the absorption of toxic gases and vapors with a diagram of representative respiratory patterns of a person exposed to a thousand parts of ammonia per million parts of air and of a person exposed to ten thousands parts of trichlorethylene per million parts of air. Carbon disulfide and benzene no longer menace the health of workers as they did ten or twenty years ago, since the hazards are recognized and controlled. However, new solvents and volatile chemicals, some of which may be capable of causing serious illness, are constantly being introduced in industry and to a lesser extent turned loose on an unsuspecting public. Disease of the liver or impairment of blood cell formation has long been associated with exposures to solvent vapors. The possibility of a toxic exposure is therefore usually thought of and investigated in patients with unexplained jaundice or with anemia or leukopenia. Many exposures to toxic vapors may fail to result in either of these reactions but may cause a nephritis that clinically is readily mistaken for ordinary glomerular nephritis. Many physicians are not aware of the frequency of toxic nephritis due to exposures to toxic chemicals and may fail to inquire about such exposure in a patient with renal disease, although they would seek to determine such exposure in a patient with anemia or evidence of seriously impaired hepatic function.

Book Notices

What You Can Do for High Blood Pressure. By Peter J. Steincrohn, M.D., F.A.C.P. Cloth. Price, $2.50. Pp. 191. Doubleday & Co., Inc., Garden City, N. Y., 1947.

It is difficult for a physician, in writing a book of medical advice for laymen, to avoid the pitfalls of being too technical or too condescending and of magnifying or minimizing symptoms unduly. In his book Dr. Steincrohn has succeeded well in keeping to the safe middle ground. In a chatty, friendly manner he discusses the influence of the emotions on blood pressure and suggests ways by which an individual can learn to control his frame of mind at least to some extent.

Most experienced physicians will agree emphatically with the author's opening statement that "more persons are concerned about the actual height of their blood pressure than with the potential dangers of the atomic bomb." They will also agree with him that "patients have become too conscious of numerals as related to blood pressure." It is unfortunate that so many persons with elevated blood pressures believe that they must have their pressure read at frequent intervals. Dr. Steincrohn pertinently says that if all physicians would stop telling patients how high their pressure is, and if all patients would stop asking, a turning point in the treatment of hypertension would be reached.

Dr. Steincrohn does not pretend to have a magic formula for reducing blood pressure but stresses the importance of keeping one's temper, of securing enough rest and sleep, of keeping one's weight within normal limits and of avoiding overexertion. Little is said about drugs, unless alcohol be considered as such. Evidently Dr. Steincrohn agrees with the late Lewellys Barker's epigram that a man is a fool if he drinks before he is 50, but a greater fool if he does not drink after that age. "A good rule is no alcohol for the intemperate, but a spot of liquor at night for those who can take it or leave it."

This book can be read by the average hypertensive patient—and by his doctor—with profit.

Neuropathology in Its Clinicopathologic Aspects. By I. Mark Scheinker, M.D., Assistant Professor of Medicine (Neurology) and Instructor in Neuropathology, University of Cincinnati College of Medicine, Cincinnati. With a foreword by Tracy J. Putnam, M.D., Professor of Neurology and Neurological Surgery, College of Physicians and Surgeons, Columbia University, New York. Cloth. Price, $6.75. Pp. 306, with 208 illustrations. Charles C Thomas, 301-327 E. Lawrence Ave., Springfield, Ill., 1947.

The material in this book is excellent and is presented in an easily understandable way. The subject matter on pathology is closely integrated with the clinical symptomatology and this makes the book desirable to have for ready reference. There are nine chapters on diseases of vascular origin, neurosyphilis, demyelinating processes, inflammatory diseases, myopathies, syringomyelia, cerebellar disorders, progressive degenerative diseases and presenile and involutional senile degeneration. This book is recommended to all medical students, practitioners of medicine and neuropsychiatrists. It has a fairly large bibliography.

Tropical Nutrition and Dietetics. By Lucius Nicholls, M.D., B.C., B.A., Director of Bacteriological and Pasteur Institutes, Colombo, Ceylon. Second edition. Cloth. Price; $7.50. Pp. 370, with 47 illustrations. Bailliere, Tindall and Cox, 7 and 8 Henrietta St., Covent Garden, London, W. C. 2, 1945.

This enlarged edition has been revised to include the more recent knowledge of nutrition. It is planned primarily for workers in tropical regions and is a reflection of conditions and practices in Ceylon and the East. The initial chapters deal with the physiology and chemistry of the basic food substances. This section is followed by detailed consideration of the individual vitamins, with useful tables of food sources and available quantities. There is a useful and extensive list of foodstuffs, including fruits and vegetables, with the corresponding energy, mineral, thiamine, vitamin A and ascorbic acid values. A brief chapter on insect pests of stored cereal and pulses is useful for the tropical worker. The treatment of the subject matter and the content of the text as a whole is oriented to the practitioner.

America's Needs and Resources: A Twentieth Century Fund Survey Which Includes Estimates for 1950 and 1960. By J. Frederic Dewhurst and Associates. Cloth. Price, $5. Pp. 812, with 42 illustrations. The Twentieth Century Fund, Inc., 330 W. 42d St., New York 18, 1947.

This book is a one volume encyclopedia of the economy of the United States. Within its pages are marshaled all the salient facts of our economic life: current trends, war lessons, the nature of needs and the dimensions of the resources with which they can be met. To this the authors have added their guesses of what our economy can produce in 1950 and in 1960.

For these guesses the book is most in demand. The authors are careful to say that theirs is no "plan" or prediction of what will happen; rather it is an estimate of what can happen in our economy if each sector functions as well in the future as it has at any time in the recent past.

Consumer requirements are discussed in nine major categories, of which medical care is one. The authors of this section—both employees of the Social Security Administration—emphasize that needs for medical care will best be satisfied by improved organization of medical services; they specify group practice as an example of this.

The volume omits consideration of the effects of continuing shipments of relief supplies to foreign countries and of the possibility of another "great depression."

Practical Clinical Psychiatry. By Edward A. Strecker, A.B., A.M., Sc.D., Professor of Psychiatry, School of Medicine, University of Pennsylvania, Philadelphia; Franklin G. Ebaugh, A.B., M.D., Professor of Psychiatry, University of Colorado School of Medicine, Denver, and Jack R. Ewalt, M.D., Professor of Neuro-Psychiatry; Director, Galveston State Psychopathic Hospital, University of Texas Medical Branch, Galveston. Section on Psychopathologic Problems of Childhood by Leo Kanner, M.D., Associate Professor of Psychiatry, Johns Hopkins University School of Medicine, Baltimore. Sixth edition. Cloth. Price, $5. Pp. 476. The Blakiston Co., 1012 Walnut St., Philadelphia 5, 1947.

This sixth edition of "Practical Clinical Psychiatry" is the best to date published by the authors. There are fourteen chapters starting with personality development and function followed by methods of psychiatric examination, the organic reaction types, toxic psychosis, the affective and schizophrenic reaction types, constitutional psychopathic inferior, paranoid reaction types and paranoia, traumatic reactions, psychoneurosis, psychosomatic medicine and pathologic drinking. The problems of childhood make up the last chapter. The authors are justified in stating that the basic idea of psychosomatic medicine is ancient. Their plea for training of all medical students in psychiatry from the first day of entrance to school should be followed. The chapter on pathologic drinking is excellent. This book is highly recommended to all medical students and practitioners of medicine.

A Synopsis of Surgical Anatomy. By Alexander Lee McGregor, M.Ch., F.R.C.S., Surgeon, Johannesburg General Hospital, Johannesburg, South Africa. With a foreword by Sir Harold J. Stiles, K.B.E., F.R.C.S. Sixth edition. Cloth. Price, $6.50. Pp. 714, with 699 illustrations by Dr. E. A. Thomas. William Wood & Co., Mt. Royal & Guilford Aves., Baltimore 2; John Wright & Sons, Ltd., 28 Orchard St., Bristol 1, England, 1946.

This is always a valuable book, presenting in schematic and outline form a complete picture of human anatomy. The previous edition appeared in 1943, and thus only minor changes are to be expected. These revisions are chiefly apparent in the increased attention to the autonomic nervous system, the relative importance of which has increased in clinical significance. As always, this work can be recommended to those seeking a concisely diagrammatic review of anatomy.

Hobday's Surgical Diseases of the Dog and Cat. Edited by James McCunn, M.R.C.V.S., M.R.C.S., L.R.C.P., Professor of Veterinary Anatomy, Royal Veterinary College, London. Fifth edition. Cloth. Price, $6. Pp. 422, with 331 illustrations. William Wood & Co., Mt. Royal & Guilford Aves., Baltimore 2, 1947.

The first edition of this standard work appeared in 1900. This new edition does not differ greatly from the earlier ones. It is a manual which lists the commonest diseases of the dog and cat which require surgical care. Diagnostic procedures are not given much attention. The descriptions of surgical technics are adequate but somewhat outmoded in some instances. The book would be of some value to those who care for animal colonies used for medical research.

Essentials of Endocrinology. By Arthur Grollman, Ph.D., M.D., F.A.C.P., Professor of Medicine and Chairman of the Department of Experimental Medicine, the Southwestern Medical College, Dallas, Texas. Second edition. Fabrikoid. Price, $10. Pp. 644, with 132 illustrations. J. B. Lippincott Co., 227 S. Sixth St., Philadelphia 5, 1947.

The author has made several previous contributions to the literature on endocrinology. There is first a brief basic survey covering the scope and history of endocrinology and the origin, nature and uses of hormones. Thereafter, the subject is dealt with under five headings:

1. Endocrine glands of the cranial cavity (hypophysis, hypothalamus, pineal).
2. The branchiogenic organs (thyroid, parathyroid, thymus).
3. The endocrine organs of the abdominal cavity (pancreas, adrenals).
4. The hormones of the reproductive system (male, female).
5. The hormones derived from nonendocrine organs.

Under each gland there is a description of the anatomy, physiology, pathology and biochemistry, also a section on clinical considerations. Some clinical sections are good, but this is the minor part of the book. Since the book was written for the general practitioner, it seems overweighted in favor of descriptions of biologic and chemical investigations. Especially is this true of the section on the hormones of the reproductive system. Although the thymus and pineal have no known endocrine function at present, they are discussed at considerable length. There are tables giving commercially available endocrine products and their standardization.

The Guarantee of Annual Wages. By A. D. H. Kaplan. Cloth. Price, $3.50. Pp. 269. The Brookings Institution, 722 Jackson Place, N. W., Washington 6, 1947.

The Brookings Institution offers here a consideration of a proposal to improve the lot of persons who work for wages; emotional erosion may be the result of workers' fear of losing their jobs. However, a measure which meets the needs of one group may injure the interests of other groups. The author explains that guaranteed annual wages are suitable for certain industries--chiefly those with predictable seasonal variation in productivity. But to force all industries into the mold would require something akin to guaranteed production plans for each industry if member firms are to stay afloat. The minimum result would be the creation of new rigidities in a price system which works best when kept flexible and new monopolistic elements in an economy that works best without dominant agencies. The maximum result would be an approach to a fully planned industrial production. With either result, consumers would be offered only the products of firms which achieved mass production without much fluctuation in output. New enterprises, particularly new products, would become conspicuous by their absence.

The author's justifiable conclusion is that guaranteed annual wages have a place in the scheme of things, but that the nation's industry should not be dosed with a medicine that works for a specialized few of its member firms.

Pharmaceutical Laboratory Manual. By R. A. Kuever, Ph.G., Ph.C., Dean of the College of Pharmacy, State University of Iowa, Iowa City. Cloth. Price, $2.75. Pp. 290. J. B. Lippincott Co., 227-231 S. 6th St., Philadelphia 5, 1947.

This compilation of one hundred and forty experiments in pharmaceutic compounding is intended for teaching pharmacy students. The experiments cover a wide range of preparations found in U. S. P. XIII and N. F. VIII, graded from the simple preparation of "waters," "solutions" and "infusions" to more complex preparations such as "vanishing cream" and "tooth paste." Many of the preparations are probably outmoded when viewed in the light of modern therapy. Each experiment leads to the production of a practical quantity of material, although the student may never later be called on to make such products. Directions for preparation and information concerning the uses and mode of administration, storage, constituents and the chemistry involved are provided for each product. A facing page of pertinent questions, with space for written answers, accompanies each experiment outline. The book contains much useful information for those pharmacy students whose interest may lie in the field of pharmaceutic manufacturing.

Lezioni di clinica medica [Vol.1°]. Di Luigi Condorelli, direttore della r. Clinica medica di Catania, Catania. Collana di scienze mediche, I. Boards. Price, 655 lire. Pp. 189, with 25 illustrations. Casa editrice A. P. E. (Azienda poligrafica editoriale), Corso Italia, 23, Catania, 1946.

Eight lectures delivered by Dr. Condorelli to his students make the content of the book. The cases chosen for discussion are of some interest, but some daring diagnoses such as that of pulmonic stenosis and patency of the ductus and that of coarctation of the aorta and patency of the ductus leave the reader perplexed on their exactness, in the absence of surgical or postmortem control and of more complete clinical work-up. The writing is redundant and verbose, and the frequent digressions from the case into entirely unrelated subjects make the presentation of material rather confused. The editorial form is commendable.

Surgical Pathology. By William Boyd, M.D., M.R.C.P., F.R.C.P., Professor of Pathology, The University of Toronto. Sixth edition. Cloth. Price, $12. Pp. 858, with 530 illustrations. W. B. Saunders Co., West Washington Square, Philadelphia 5, 1947.

It is interesting to compare this edition with the one of ten years ago. The space devoted to infections is now considerably smaller, as visible tribute to the effectiveness of the antibiotics. The chapter on shock has likewise shrunk, plasma and the blood bank having diminished the pathologists' supply of material from these sources. Thus the pathologist quickly reflects the trends of modern surgery. Congenital cardiac deformities, inaccessible lesions and obscure tumors of that era all are now within the surgeon's domain. The revisions made in this volume are needed to keep pace with the giant strides of modern medicine. It is heartening to see so many changes where least expected. The author has managed, as usual, to keep abreast of the tide and is maintaining the eminent place in pathology he long since attained.

Synopsis of Operative Surgery. By H. E. Mobley, M.D., F.A.C.S., Chief of Surgery at St. Anthony's Hospital, Morrilton, Ark. Second edition. Fabrikoid. Price, $6. Pp. 416, with 383 illustrations. C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3, 1947.

Because this book contains "acute appendicitis is usually best handled by packing with ice, keeping the patient quiet and at rest for a few days until the acute inflamed condition subsides" it is not worth reviewing for scientific purposes.

Hospital and Public Health Resources in New Jersey: A Source Book. Part 1 of Report of New Jersey Survey of Hospital and Health Center Facilities under Federal Hospital Survey and Construction Act. Paper. Pp. 114, with illustrations. State of New Jersey, Department of Institutions and Agencies, Trenton, 1947.

Congress passed the Federal Hospital Survey and Construction Act to assist the several states in taking inventory of their existing hospitals, in surveying the need for construction of more hospitals and in developing programs for public and nonprofit hospitals. When completed, in combination with the present facilities, these programs should meet the need of adequate physical facilities capable of furnishing adequate services to all their inhabitants. The final step in this program is to construct the hospitals found to be needed.

In New Jersey (the state described in this pamphlet) the Department of Institutions and Agencies was assigned the task of administering the federal program. It is the duty of this department to present a plan showing the over-all need for additional hospitals and public health centers in the state. As this plan is being evolved, the department has issued this pamphlet as a source book. It contains information about all types of facilities for medical care available in New Jersey. This study presents a precise and complete view of the type and extent of services by hospitals, physicians, dentists, nurses, pharmacists and public health services in the state.

In regard to the general problem of meeting mounting hospital deficits and securing adequate reimbursement by the hospitals for the care of the indigent patient, the following is taken from a study recently made by the New Jersey Hospital Association and the New Jersey Department of Institutions and Agencies: "Only through governmental payments can the hospitals continue to furnish the service on which communities have come increasingly to depend as a central feature of the total health and welfare program."

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

SECONDARY ANEMIA IN THE AGED

To the Editor:—Is folic acid indicated and has it any beneficial effect in the treatment of secondary anemia in a patient with advanced arteriosclerosis who is 82 years of age? Are there toxic side reactions?

Captain, M.C., U. S. Army.

Answer.—No reason exists for anticipating toxic manifestations from the moderate administration of folic acid to persons at any age. Though it is impossible to be certain that folic acid will be helpful to the patient cited in the query because of lack of precise information, it is highly probable that it will be helpful. Parenteral liver extract is more promising, however. In older persons one observes mixed forms of disorders more frequently than pure types. Diagnosis of specific disease entities in the elderly can be carried too far. For example, anemia is frequently due to both a nutritional (raw material) deficiency and a primary hemopoietic inadequacy. Unless both conditions are treated therapy is only partially successful. Similarly, many instances of chronic hypertrophic arthritis in later years are complicated by superimposed gout which is seldom discovered. Anemia even of minor degree in a patient aged 82 with advanced arteriosclerosis is a serious handicap: with loss of vascular flexibility the quality of the circulating blood becomes increasingly significant. Small (250 cc.) transfusions of blood followed by antianemic therapy are frequently helpful.

DIET IN TUBERCULOSIS

To the Editor:—In obese patients with pulmonary tuberculosis treated by rest in bed can weight be reduced to near normal without danger? What should be the composition of the diet, and how many calories per day, or per pound per day, should be allowed? The patient is 30 years of age, 6 feet 1 inch (185.42 cm.) tall and weighs 235 pounds (106.6 Kg.). How fast can the weight be reduced, and what should final weight be? Are high protein diets and high vitamin A diets as well as diets high in calcium and phosphorus of any therapeutic value in pulmonary tuberculosis?

M.D., Michigan.

Answer.—The main object in the dietetic treatment of the tuberculous patient is to enable him to regain his lost weight but not to make him unnecessarily fat. The weight of an obese tuberculous patient can be safely reduced at the rate of 3 to 4 pounds (1.4 to 1.8 Kg.) per month, and his ideal weight is about 10 pounds (4.5 Kg.) above the average weight for his age and height. A reduction diet must include an increased supply of vitamin A and ascorbic acid to preserve nutritive equilibrium. Protein requirement is estimated at 1.5 to 1.75 Gm. per kilogram of body weight (Fishberg, M.: Pulmonary Tuberculosis, ed. 4, Philadelphia, Lea & Febiger, 1932, vol. 2), and carbohydrates should furnish about 40 per cent of the caloric requirements. The healthy person at complete rest requires 15 calories per pound (Goldberg, B.: Clinical Tuberculosis, ed. 5, Philadelphia, F. A. Davis Company, 1946, vol. 1) and from this standard a reduction diet can be estimated at the discretion of the physician. The patient's sense of well-being and satisfaction are factors to be considered. Thyroid extracts and amphetamine compounds are contraindicated. Diets rich in minerals have no proved value in the treatment of tuberculosis.

FLUOROSCOPY OF INFANTS

To the Editor:—Some pediatricians fluoroscope the infant at every monthly visit. What are the indications for fluoroscoping a child during the first year of life?

M.D., New York.

Answer.—It is generally considered good pediatric practice to fluoroscope an infant at the first office visit, usually when the child is 1 month of age. A few good pediatricians do not use a fluoroscope at all, except in the case of a sick infant. If no abnormalities are observed at the first fluoroscopic examination, it is unnecessary to refluoroscope the infant for a year or two, unless an illness develops that requires fluoroscopic aid in diagnosis. If at the first fluoroscopic examination an abnormality is observed such as a wide mediastinal shadow, enlarged heart or abnormal epiphysial development then progress might be observed every few months using the fluoroscope. Fluoroscopy of a well baby every month is bad practice because of the danger of repeated exposure to roentgen rays with their harmful effects.

AMENORRHEA

To the Editor:—A white woman aged 24 last had a regular menstrual period seventeen months ago. She started to menstruate at 13 years of age. The interval, duration and absence of cramps were all perfectly normal. Seventeen months ago the interval went from twenty-eight days to two or three months on two or three occasions, and then she stopped flowing. Her husband was overseas. The physical examination revealed a corpus which was slightly smaller than normal. Her basal metabolic rate was found to be minus 21 per cent and her red blood cell count was 4,100,000.

Therapy has consisted of an iron preparation, which has corrected her anemia, and thyroid which has brought her basal metabolic rate up to plus 1 per cent. She has been given three courses of "gonadogen" (a gonad-stimulating substance from serum of pregnant mares) in an attempt to establish a normal cycle. A day was assumed to be the first of a cycle and 10 units were given subcutaneously for fourteen consecutive days; in the event that she began to flow on or about the twenty-eighth day, the drug then would have been given similarly for fourteen more days. She did not flow spontaneously, so on the thirty-fifth day after the first dose or the first course or gonadotropic therapy the second fourteen day course was given. Daily 0.05 Gm. of ethinyl estradiol was taken by mouth for fourteen days concurrently with the gonad-stimulating substance. Then on the fifteenth, sixteenth and seventeenth days 10 units of progesterone was given parenterally. Three days after the last dose of progesterone she had a normal flow, the first in sixteen months. The record of daily basal temperatures before arising each morning has revealed that ovulation is not taking place, so this flow was probably on the basis of deprivation of progesterone in the presence of the estrogenic substance which had been taken by mouth.

Are any other measures suggested? She has not ovulated this third cycle. Ten units of the gonadotropic substance were given daily with the first day of flow, and then it was continued for fourteen days; no estrogen or progesterone has been given this time because, inasmuch as she is not ovulating, any flow would simply be based on deprivation of progesterone and not on ovulation.

M.D., California.

Answer.—As the amenorrhea in this patient is approximately of a year and a half's duration, it appears that there is some organic disturbance of the ovaries, since functional amenorrhea seldom lasts this long. Endometrial biopsies or even vaginal smears would be useful in indicating the degree of ovarian function. The refractoriness of the ovaries to gonadotropic therapy is confirmatory of the idea that the ovaries are damaged although gonadotropic therapy is at present on a rather unsatisfactory basis. Substitution therapy with ovarian hormones, estrogen and progesterone could probably cause a menstrual flow simulating the true cyclic bleeding when properly administered, but this does not relieve the basic condition. The suggestion is made that if it is possible a pelvic peritoneogram be made to demonstrate the size of the ovaries. Atropic ovaries would indicate the possibility of an irreversible condition. If the ovaries are normal in size or even moderately enlarged, it is possible that they are encased in a fibrous capsule which suppresses the cyclic activity of the ovaries. Such a condition often responds to partial resection of the ovaries with normal menstruation.

PHANTOM LIMB

To the Editor:—I have a patient who had a midthigh amputation eighteen months ago. He complains of moderate pain in the stump and of phantom limb. He has an artificial limb which he does not wear much. I have injected procaine hydrochloride and "trithesia (oil solution)" (propyl para-aminobenzoate 4 per cent; procaine base 1.5 per cent, and benzyl alcohol 5 per cent) a few times with only short relief. He resorts to alcohol or opiate at times for temporary relief. Please advise treatment.

G. C. Chamness, M.D., Zeigler, Ill.

Answer.—There is no conservative treatment for your case that will permanently relieve your patient of pain. If the latter is severe enough to cause him to take opiates and alcohol it is suggested that he have a competent neurosurgeon decorticate the area of the opposite postcentral gyrus receiving painful sensations from the involved thigh. This should produce complete loss of pain in the stump and in the phantom limb. This type of complication following amputations is not common. It is due, undoubtedly, to central processes which have no organic foundation in the central nervous system but in the peripheral nervous system. After the amputation there is irritation of the central conducting axons within a neuroma or at the proximal end of a freshly cut mixed nerve. These are the axons that formerly brought impulses to the higher centers from the part which has been amputated. Even after this irritation is removed the abnormal reflexes previously provoked continue to cause the sensations and pain. Such complicating symptoms can be prevented by placing a nonabsorbable ligature tightly around the uninjured nerve trunk about 1 inch (2.54 cm.) above the amputation site at the time of the amputation. An excellent article on the subject by Louis G. Herrmann and Edward W. Gibbs appeared in the *American Journal of Surgery* (**47:168** [Feb.] 1940).

CONGENITAL MEGACOLON

To the Editor:—A boy aged 5 years was operated on for megacolon about six months ago because medical treatment was inadequate. The entire colon down to the rectosigmoid junction was removed and an ileocolostomy established using a Rankin clamp. The Rankin clamp was later removed and a fecal fistula was established. The patient had an enormous dilatation of his entire descending colon and about one-half of his transverse colon. Following the colectomy he was bothered considerably with distention. Discharges from the ileostomy were liquid in character. Distention was finally brought under control by the use of prostigmine. After thirty days the ileocolostomy was closed, supposedly in a satisfactory manner, but it reopened and was closed a second time. After the second closure the patient had bowel movements, liquid in character, and he again became distended. This condition was relieved by administration of prostigmine intramuscularly and orally. However, his ileocolostomy again broke down, and at present he has a small opening through which a great deal of fecal matter drains. At times he has a fairly normal bowel movement. His distention has gradually subsided, but his bowel movements continue to be soft and liquid. He has received prostigmine up until the last month and has gradually gained weight. He eats almost anything and feels well. I will close the opening of the ileocolostomy some time in the near future. Why do his bowel movements continue to be liquid and why has he had such an enormous amount of dilatation? Modifying his diet and using various preparations, including opiates, have had no effect on his stool. There is no reason to suspect an obstruction at the juncture of the ileum and rectum.

M.D., North Dakota.

Answer.—In congenital idiopathic megacolon there is, in addition to dilatation and hypertrophy of the bowel, a contraction of the rectosigmoid sphincter, the sphincter O'Beirne, and it is possible that the remaining distention in this instance and the reason for the breakdown of the ileocolostomy is because of the relative obstruction produced at this point. It is suggested that forceful dilation of the anal and rectosigmoidal sphincters be performed. This will probably permit the satisfactory closure of the fistula and will overcome the distention. The diarrhea is likely to persist for some time, because after a total colectomy the ileum does not take over the function of the large bowel. For this reason it would probably have been better not to have removed the entire colon but to have left a portion of the ascending colon at the time of the original operation. It is possible that the remaining portion of the rectosigmoid may take over the function of the colon sufficiently to permit the child to get along fairly well without too many bowel evacuations.

BILINGUAL CHILDREN

To the Editor:—I have been asked to solve the following problem: Should a couple of foreign birth (German) who speak their native language and English equally well try to teach their child, 1 year of age, both languages at the same time or teach him the foreign language later at the age of 5 or 6? As there seems to be some doubt as to the ability of the average child to learn two languages, would not an attempt at this lead to (1) retardation of development of speech in both languages; (2) due to the two languages having many similarities, the development of a mixture which may be hard to correct later, or (3) due to the inability to express himself according to his age, emotional maladjustment or even retardation of mental development?

M.D., Illinois.

Answer.—Prevailing opinion is that the child should be taught the single language, English, during its first five years. While many children can, and do, become bilingual in their early years without difficulty, there is a chance that any particular child might develop neurotic tendencies because of the bilingual pressure. In answer to the specific questions: (1) the average child (one with average intellectual ability and average auditory discrimination) might very well show a retardation or withdrawal from language due to the dual pressure; (2) a mixture of the two languages might occur if the pressure for perfection was severe in the home, leading to a relaxation away from the home, and (3) emotional maladjustment might well follow the conflict established in the child's mind by the dual language pressure, though it is questionable whether there would be mental retardation due to the attempt.

DISTILLED DRINKING WATER

To the Editor:—We are attempting to obtain information on the effects on infants and children of drinking distilled water over extended periods of time. Please supply reports or information on this subject.

J. P. Holt, M.D., New York.

Answer.—As long as an infant is ingesting milk, either human milk or customary formulas of cow's milk, and is retaining it, the intake of mineral salts will be ample with some to spare, so that he does not have to depend on the mineral content of the water consumed. Consequently distilled water would have no influence for good or evil. In an older child the absence of iodine and fluoride from distilled water might conceivably influence the development of goiter or dental caries. The fluorine ingested in foods is utilized much less than that in water. Distilled water per se would have no unfavorable influence provided the child were otherwise on a normal well balanced diet.

STREPTOMYCIN IN TUBERCULOSIS

To the Editor:—I am treating 7 patients with progressive pulmonary tuberculosis with streptomycin. Each has extrapulmonary tuberculosis; 2 have involvement of the spine and cold abscess formation. The others have either tuberculous laryngitis or a tuberculous fistula in ano. Treatment was discontinued in 2 patients because of dermatitis, headache and decided elevation of temperature. Vestibular disturbance occurred in all patients but was serious only in 1. Hypochromic macrocytic anemia has developed in all cases. The red blood cell count is 4,000,000 to 5,000,000 in all cases. Sahli hemoglobin determination is 70 to 45 per cent. Liver extract (10 units biweekly), liver and iron, ferrous sulfate alone, and folic acid have not helped. Is the hemoglobin reduction permanent? What therapeutic measures are indicated? Streptomycin sulfate was used in all cases. Is the hydrochloride better? The treatment period was one to four months. Results in those receiving 1.5 to 2 Gm. a day for two months have been dramatic. Is there a technic for desensitization of patients that have dermatitis?

M.D., Hawaii.

Answer.—G. L. Muller (Clinical Significance of the Blood in Tuberculosis, New York, the Commonwealth Fund, 1943. p. 215, 217) found an anemia (hemoglobin below 12 Gm. per hundred cubic centimeters) in 22 per cent of 1,130 patients with tuberculosis. Of those with anemia, 8.4 per cent had a macrocytic hypochromic type. A generalized intoxication is probably the most important etiologic factor. Indirect evidence for this is offered in the query by the failure of the patients to respond to liver, folic acid or iron therapy. If these patients have a megaloblastic bone marrow, folic acid and oral aqueous liver extract should receive further trial. The hemoglobin level should increase with improvement in the infection.

A recent report by the Veterans Administration, the Army and the Navy (The Effect of Streptomycin on Tuberculosis in Man, Preliminary Statement, *J.A.M.A.* **135:**634 [Nov. 8] 1947) and another by Farrington and co-workers (Farrington, R. F.; Hull-Smith, H.; Bunn, P. A., and McDermott, W.: Streptomycin Toxicity: Reactions to Highly Purified Drug on Long-Continued Administration to Human Subjects, *ibid.* **134:**679 [June 21] 1947) indicate that anemia is not a toxic manifestation of streptomycin therapy. The latter authors point out that identical toxic symptoms occur with streptomycin hydrochloride as with the sulfate.

No report was found of a technic for desensitizing patients to streptomycin. The pruritus associated with dermatitis is usually relieved by diphenhydramine hydrochloride ("benadryl hydrochloride"). Administration of streptomycin should be discontinued if exfoliative dermatitis occurs.

STREPTOMYCIN USED INTRAPERITONEALLY

To the Editor:—Is it advisable to put a solution of streptomycin in the peritoneal space around the cecum after removing an appendix covered with exudate or a perforated appendix?

John P. Gifford, M.D., Vero Beach, Fla.

Answer.—It is permissible to use streptomycin locally in the peritoneal space around the cecum after removing an appendix covered with exudate or a perforated appendix. It would be better, however, to inject streptomycin intramuscularly in amounts of 1 Gm. daily in divided doses every twelve hours for at least ten days when localized peritonitis is present. Parenteral therapy is always preferable to local treatment, and it is commonly more effective.

CYANIDE POISONING

To the Editor:—I read with interest your reply to the inquiry on cyanide poisoning in *The Journal,* Nov. 29, 1947, page 878. An error appears with regard to the chemistry of calcium cyanide. Calcium cyanide in the presence of moisture hydrolyzes rather rapidly, liberating hydrogen cyanide or hydrocyanic acid. This compound is not a skin irritant, although it may be absorbed through the skin. Cyanogen is not liberated from calcium cyanide on exposure to the moisture of the air. Cyanogen may be obtained from certain of the cyanides with difficulty, for example, on heating mercuric cyanide. Also, the reaction of potassium cyanide with copper sulfate yields cyanogen. Likewise, the dehydration of ammonium oxalate by means of phosphorus pentoxide liberates this compound.

Certain plants manufacture large quantities of hydrocyanic acid and its salts. Inevitably, a few accidents occur each year which result in acute hydrocyanic acid poisoning. Some of these cases have been rather severe, but in each instance the condition has responded more or less rapidly to the treatment suggested by Chen and his co-workers, i. e., the inhalation of amyl nitrite with artificial respiration, followed by the intravenous administration of sodium nitrite and sodium thiosulfate. In some cases unconsciousness has lasted for as long as eight hours. These cases, therefore, have given plant physicians an opportunity for accurate clinical observations. It is their considered opinion that such poisoning is an "all or none" type—that is, the patient either dies or recovers completely with no demonstrable residual pathologic condition.

They also believe that chronic cyanide poisoning does not exist, since small quantities of cyanide are detoxified so rapidly and completely, the cyanide apparently being converted to thiocyanates.

THE PRESENT STATUS OF VIRUSES AND VIRUS DISEASES

EDWIN W. SCHULTZ, M.D.
Stanford University, Calif.

A hundred years ago the existence of viruses was unknown. The beginning of knowledge of this group of infectious agents indeed goes back only a half century. It is not yet fifty years since Beijerinck [1] established that the infectious agent of tobacco mosaic disease is filtrable and called it a "contagious living fluid" and since Loeffler and Frosch [2] identified the first ascertained virus disease of animals, foot-and-mouth disease. In the decade or so which followed a small number of other plant and animal diseases were identified as of virus origin. Among these were yellow fever, rabies, vaccinia-variola and poliomyelitis. But while the boundaries of knowledge regarding virus diseases widened gradually from this beginning, it was not until shortly after the first World War that the advances became rapid. This new period was ushered in by the discovery that bacteria, the outstanding partners of viruses in causing infections, are themselves victims of a virus disease. At first there was some uncertainty as to whether this disease, bacteriophagy or the Twort-d'Herelle phenomenon,[3] could be classified along with other then known virus diseases. It was viewed with caution by many. The precise nature of the agent responsible became the subject of warm debate, and one might ask today how much d'Herelle's staunch advocacy of bacteriophage as a living "ultramicrobe" had to do with the acceleration of interest in viruses which took root in the early twenties. Certainly bacteriophagy afforded an opportunity to study a virus disease under relatively simple and inexpensive conditions and still affords a favored approach to some of the unsolved problems in the virus field.[3f]

Whatever may be said regarding the stimulus which prompted the rapidly widening interest, the advances which have been made in knowledge of viruses during the past quarter of a century are little short of phenomenal. Many of these advances have been summarized in manuals, monographs and reviews.[4] No little of this advance can be credited to the professional pathologists, but a great deal must also be credited to men who set out to be chemists and physicists but later found themselves at the side of the animal and plant pathologists, dealing with aspects of problems which they alone were prepared to handle. Nowhere else in the advance of medical science was the need for cooperative effort greater, and nowhere else have the results proved more gratifying. What then have been the accomplishments of these years? What do men know with reasonable certainty about these agents, and what are some of the problems which remain unsolved? It is obvious to every one here, I know, that the achievements of a quarter of a century can scarcely be summed up in a quarter of an hour. I can recall only vaguely how I was led into this impossible task. There are, of course, moments far in advance of meetings when titles appear less ominous.

Men know today that virus infections are widespread. The invasion stretches from such lowly forms as bacteria to man. Many of the groups attacked by viruses are known to suffer with more than one virus disease. Bacteria are involved not by one but by many viruses—viruses which are distinguishable from each other in species or strain specificity, in size, in antigenic constitution and in other respects.[3] In other words, an impressive array of viruses attack bacteria alone. It is not known that there are viruses which attack protozoa, but to find that these forms also are included would not be surprising. In the plant kingdom many species of plants are known to be singled out by viruses of one kind or another,[5] and the studies which have been carried out in this area alone have advanced knowledge of viruses more than can be estimated. The

virus of tobacco mosaic disease was not only the first virus to be identified, but the first to be obtained in a purified form. This was the accomplishment of Wendell M. Stanley,[6] a chemist, who obtained the virus in a paracrystalline form in 1935, twelve years ago. This achievement marked the beginning of a new era in the study of viruses, one in which purification and more complete analysis of their individual properties became an important part of subsequent progress. For his achievement in virus chemistry Stanley was awarded the Nobel Prize last year.

In the animal kingdom the forms which are attacked range from insects to man. In many instances, the infections caused are strictly limited to one species or type of host, while in others the same viruses reach into quite unrelated hosts. In some cases the infections induced are apparently always associated with clinical manifestations; in others the infections are often apparent in one type of host and inapparent in another. The recognition that infections may occur in some hosts in a clinically inapparent form constitutes one of the important advances in the epidemiology of virus diseases. To know that a virus which attacks one type of host with devastating effect has or may have a silent reservoir in some other host is in itself a weapon against that virus. Inapparent infections are now known to be widespread. They have been recognized not only in animals but in higher plants and bacterial forms as well.[7]

There have been advances in the devices used for the study of viruses. The discovery of viruses may be credited to the use of bacteria-tight filters, such as are used to separate bacterial toxins from the organisms in a medium. It was Iwanowski's[8] apparent failure to catch the significance of his filtration results in the study of tobacco mosaic disease six years before Beijerinck made his observations which leaves him with a doubtful right to be regarded as the discoverer of filtrable viruses. At any rate, for a number of years virtually all that was known about viruses was that they passed bacterial filters. Nothing was known regarding their size, form and structure, and it is not surprising that Beijerinck in 1898 regarded the tobacco mosaic virus as something in true solution. The science of colloid chemistry was then still unborn. Investigators now have direct as well as indirect means of determining virus size and form. Collodion membranes gave the first information as to size—information which later proved more accurate than many had believed. This is a tribute to the colloid chemists who figured in this development, and particularly to Elford,[9] who provided the refinements necessary for dependable results. The next important development was the electron microscope.[10] It confirmed the fact that individual viruses differ widely not only in size (anywhere from 300 down to 10 microns) but in form and internal structure as well. It is now known that not all are spherical but that some are cuboidal or rectangular,[11] others rod shaped,[12] still others sperm shaped[13] and that certain ones are of highly irregular form.[14] The electron microscope has revealed that some viruses possess distinctive internal structure,[15] indicated in general by denser portions within their substance, and suggest a cellular type of organization.

Of equally great importance among the new tools of virus research are those which have been developed for the purification and physicochemical analysis of viruses. Although Stanley in 1935 first purified the tobacco mosaic virus by wholly chemical means, its purification was later more easily effected by differential ultracentrifugation,[16] which was made possible by the development of a new air turbine in a vacuum quantity centrifuge.[17] Out of this air driven quantity centrifuge evolved one of the current types of analytic centrifuges, with which it became possible to determine the homogeneity of supposedly purified virus suspensions, the molecular weight of a virus, its size or its density.[18] Other tools of modern chemistry and biophysics have also been pressed into use,[18c] and the sensitive methods of serology have been employed to reveal differences in their antigenic constitution.[19] Some of the advances and the remaining problems in this general area have recently been outlined by Wyckoff.[20]

Viruses are characterized in part by their dependence on living cells. None are able to grow in the absence of living cells, but this requirement has not prevented the cultivation of many of them apart from their hosts. This problem was met by drawing on the experiences of tissue culturists, and a number of viruses have now been cultivated in the presence of tissue explants. Some have been found to grow in the mere presence of living cells, free and unanchored in a suitable fluid medium,[21] but probably the greatest advance in the cultivation of viruses was the discovery by Goodpasture[22] that the developing egg can be effectively used to propagate them. This method as modified by Burnet[23] has now been successfully applied to a considerable number of viruses. It has found application in the production of viruses for use as vaccines, in the titration of viruses (in which it substitutes for animals), in serologic studies and in the diagnosis of some virus diseases.[24]

A striking feature of viruses is their heterogeneity when considered as a group. They frequently exhibit marked differences in the degrees to which they resist certain physical and chemical agents. Extensive studies have made it clear that they are "individualists" and that generalizations from observations on any one of them are apt to rest insecurely. They are not alike in their resistance to heat, cold, drying, hydrogen ion concentrations, organic or inorganic chemical compounds, or to the action of individual enzymes.[25] They are not alike in their chemical constitution or in their biochemical properties.[26] There are resemblances, as well as differences, of course, but taken as a whole they are quite as heterogeneous in makeup and properties as the various hosts they prey on.

They differ in their individual tropisms; that is, in the particular types of cells which they single out for invasion and subsequent multiplication. This usually means some kind or kinds of cells within some particular host. This tropism is apt to be a fairly constant property of a given virus. Observers have become aware, however, that the tropism of a virus may be much less restricted and less fixed than they are sometimes led to believe and that it is also subject to variation.[27] This variation may depend on only slight tissue or environmental differences. The conversion of street rabies virus into fixed virus by brain to brain passage is associated with a loss of ability of the virus to implant itself in peripheral nerves. The variation may reach to new cells or tissues, sometimes with complete loss of the initial tropism. It may occur independently of variation in the antigenic constitution of a virus.

What determines the tropism of a virus is something about which little is known. There is some evidence from observations on bacteriophagy that the antigenic constitution of the host cell and susceptibility to a given virus are related.[28] Since antigenic constitution may be largely determined by genetic factors, it may not be possible to do much artificially to alter these natural relationships. This is an area in which further work is needed.

Variations are also exhibited by viruses in other respects,[29] including variation of their antigenic constitution. The latter may be associated with variation of tropism or may occur independently of it. Variation of antigenic constitution has an important bearing on the serologic identification of viruses. Investigators have learned that viruses which cause individual diseases may fall into different serologic groups and that variation may result from new environmental conditions which are imposed on the virus. Such variations fortunately do not as a rule occur with great ease, so that it has been possible to base much of what is known today about differences among viruses on serologic observations.

Viruses differ in their individual proliferative powers. There are low and high titer viruses. These differences relate not only to viruses causing different diseases but also to individual strains of a given virus. They may not be the same for a given strain when it is propagated in another host, but they tend to become stabilized for a given host and frequently remain the same for it in spite of many serial passages. Little is known regarding the factors which determine these individual differences. They appear to be represented in both the host and the parasite. Low titer strains may not lack in invasiveness and, like more virulent strains, may become widely disseminated in the tissues of the respective hosts, but they seem to lack the ability to multiply sufficiently within the cells they invade to damage them seriously. Such strains may be partly responsible for subclinical infections and naturally acquired active immunity to individual virus diseases.

Little is known about how viruses act to produce their harmful effects on the cells they invade, since they are not as a whole identified with toxic properties. More information is needed in this area.

Since viruses exhibit cell tropisms, the lesions induced center around individual kinds of cells. The effects produced on these cells can and do differ widely. Considering viruses as a whole, these effects range from rapid cell death to mere stimulation of cell growth and multiplication, the latter being a characteristic of the tumor group.[30] To state the effects so broadly is to oversimplify the story somewhat.[31] The distinctive lesion is at any rate an involvement of some kind of cell. Whatever inflammatory reaction may be present is there as a secondary response to this cell injury.

Viruses differ also with regard to the production of inclusion bodies. Some give rise to them; others do not. Those which do, may produce them either in the cytoplasm of the cell or in the nucleus. The cytoplasmic inclusions produced by some viruses consist largely of aggregations of virus particles; those produced by certain other viruses (rabies) seem to consist chiefly of retrograde products derived from the cell itself. In certain virus diseases of plants (tobacco mosaic disease) amorphous cytoplasmic inclusions have been observed to give rise to crystalline inclusions consisting of "virus protein." [32] Nuclear inclusions also differ, the more indicative of a virus infection being the type A inclusions described by Cowdry.[33] Cell inclusions of certain types may be formed in the apparent absence of virus infections, and these "nonspecific inclusions" must, of course, be differentiated from those which are specific.[32] Any formation of inclusion bodies must require time. They are therefore not expected in cells which succumb quickly to the impact of a virus. They are, on the other hand, not necessarily produced in cells which resist the action of a virus. They are helpful when present and characteristic, but their absence does not exclude the possible presence of a virus infection.

Clinically, virus diseases are about as varied as any other group of infectious diseases. There is nothing especially distinctive about many of them. While some can easily be diagnosed clinically, others definitely require laboratory help. This is particularly true of the neurotropic virus diseases, which often cannot be differentiated without such aid. Some virus infections seem to occur regularly in a clinically evident form; others may occur in a subclinical as well as a clinically apparent form in the same type of host, and still others, in an apparent form in one type of host and an inapparent one in another. It is obvious that the existence of mild or inapparent infections cannot be recognized without laboratory help.

The laboratory procedures that aid in the diagnosis of virus diseases have advanced considerably over those of even a decade ago. They are, however, for the most part highly specialized and not of the kind which can usually be rendered by the ordinary clinical laboratory. Special facilities and a suitably trained personnel are required. The procedures are varied but in general consist either of attempts to effect a direct isolation and identification of the virus or of tests that reveal whether or not viral antibodies are in the patient's blood.[34] The latter may mean tests for virus-neutralizing antibodies or wholly in vitro tests for complement-fixing or agglutinating antibodies. The first-named type is based on inactivation of virus and is therefore partly an in vivo test carried out with susceptible experimental hosts. Wholly in vitro tests, such as the complement fixation test, are much more convenient and less costly than neutralization tests, but unfortunately they are not as uniformly applicable to the diagnosis of virus diseases. A certain minimum amount of virus material must be present in the antigen that is used in such a test, and this is something not easily realized with materials representing all kinds of virus infections. However, the complement fixation test, which is the more sensitive of the two in vitro tests named, has proved its value in the diagnosis of several virus diseases.[35] Even with the more generally serviceable neutralization test it is important to bear in mind that antibodies often do not make their appearance in the patient's blood until late in the disease or after recovery. A large part of the value of these tests therefore lies in the identification of the cause of a past infection rather than that of a current illness. In any case it is important to procure a specimen of serum early during the course of a patient's illness, for comparison with later specimens.[34b]

One of the largely unsolved problems in regard to virus diseases is that of specific therapy. Any sort of direct attack is complicated by the fact that viruses are intracellular infectious agents, also by the fact that the initial invasion is likely to be widespread and to involve many susceptible cells simultaneously. Once a virus particle has found its abode within a cell, it is apparently out of the reach of potential therapeutic agents which may thereafter be brought to the environment of the cell. Unlike intercellular bacterial parasites, it is no longer exposed to whatever may be successfully conveyed to the area by the blood. Antibody molecules are too large to follow the virus into the cell, and chemical agents which might conceivably do so and there inhibit or destroy it, would seem likely to injure the cell also. The problem is therefore a difficult one. However, in spite of the theoretic difficulties presented by this intracellular relationship, hopeful chemotherapeutic results have recently been reported, following the administration of sulfonamide compounds and of penicillin, in certain individual virus and rickettsial infections, suggesting that such a direct approach may not be entirely out of the question.[36] The solution of this problem may have to be sought, however, in the form not of direct but of indirect measures—measures which may serve to make the protoplasm of the cell less suitable for the multiplication of the entrenched virus or less vulnerable to its effects. It is possible, of course, that the factors which determine the character of the protoplasmic soil and its susceptibility to a given virus are largely genetic in nature and to this extent out of artificial control, but whatever may be possible by such indirect means would seem to be in greater harmony with the normal physiology of a cell than any attempt to attack the virus directly.

Much of the control maintained over virus diseases is rooted in their immunity relationships. Because individual viruses are more or less highly dependent on suitable cell pabula, differences of the protoplasmic soil, or natural immunity, constitute one of the limiting factors. Virus infections, when they occur, moreover, are characterized by the solidity and the durability of the immunity which they leave in their wake, there being few exceptions to this rule. The immunities which follow natural infections are commonly associated with antibodies that appear in the blood. It is generally held, however, that the initial stimulus leading to their formation is not wholly responsible for the durable immunity and that this would probably not last nearly as long were it not for the fact that, following many and possibly most virus diseases, some virus persists in the recovered host and serves to keep the immunity alive.[37] This thought—that there is persistence of virus after recovery—impresses one at first as an incongruity, but the matter clears up when one recalls that viruses are ordinarily intracellular and that antibody molecules cannot reach into cells. In addition to the role played by antibodies, there may be changes induced in the protoplasm of the naturally susceptible cells (acquired tissue immunity). The evidence for this consists of the acquired resistance following certain virus infections which have been demonstrated in the absence of antibodies, either before these had an opportunity to appear, or in types of infection in which antibodies seldom are found in the blood after recovery; also, observations have been recorded showing that a high antibody level is not always associated with a high degree of resistance.[37]

[37] Rivers, T. M.: Immunological and Serological Phenomena of Virus Diseases, in Lane Medical Lectures: Viruses and Virus Diseases, Stanford University, Calif., Stanford University Press, 1939, p. 53.

Effective immunization seems to require the use of active virus, but strains safe enough to be used as vaccines are few. Vaccinia virus, fixed rabies virus and strain 17D yellow fever virus are three outstanding examples. But while there are few such vaccines available, it has proved possible to establish immunities of short duration against some virus diseases by the use of suspensions of inactivated viruses. Influenza and equine encephalomyelitis are among the diseases which have recently been brought into this fold. This use of inactivated viruses cannot do more than set up a certain level of antibody formation, and since the response tends to die down in the absence of a persistent stimulus, such as may result from a previous infection or may be induced by inoculation of active virus, the immunizations require repetition, possibly at intervals of six months to a year, to maintain their effectiveness.

Regarding passive immunity, it is well recognized that such antibodies as a prospective mother may happen to possess for given viruses are frequently transferred to the fetus and that they may convey to it a degree of protection which will endure for some months after its birth. Passive immunity can also be induced artificially against certain virus diseases. Indeed, it is preceding exposures to viruses that antiserums serve their greatest usefulness, for once a virus particle has found the interior of a cell it is out of reach and remains so unless its house falls. While immune serums have prophylactic value, their prophylactic use has been limited, one of the reasons being that it is often difficult to say whether immune serum is required or not. The patient may already be immune. There are virtually no simple tests for determining this. Recently evidence has been obtained that cutaneous allergy accompanies naturally acquired active immunity in cases of mumps,[38] apparently in the same way that allergy follows successful smallpox vaccination, but sufficient observations have been made on other virus diseases to indicate that cutaneous allergy is not always easily demonstrable after recovery. It is clear, of course, that whenever immune serum is used prophylactically, even in amounts which will prevent infection entirely, it will probably leave the recipient fully susceptible again after the passive protection has worn off. In the use of human measles immune serum, for example, the objective is to abort the infection but not to prevent it entirely.

Much of the control that is now exercised over virus diseases rests on the epidemiology[39] of these diseases. Much information has been gathered in these years, but much more is needed to enable physicians to deal with certain virus diseases, such as poliomyelitis. It is known that some are commonly spread by direct or indirect contact, and that some are transmitted by insects. The role of the latter in the virus diseases of animals and plants has been the subject of extensive investigations over a number of years and has assumed increasing importance with the recognition that vast silent reservoirs of inapparent infections may sometimes exist in hosts quite unrelated to the ones in which clinical manifestations are more common—reservoirs from which insect vectors can carry the infection to more susceptible hosts. The detection of these reservoirs investigators usually owe first to serologic observations made on potential hosts and later to successful attempts to isolate the virus from them. With improvements of serologic methods, such as the wider and more effective use of the complement fixation test, these reservoirs will become easier to identify.

I have merely touched here and there on the present state of knowledge of viruses. It was not possible to do more. One may be sure, however, that the science of virology has reached maturity and that it will be equal to the problems which remain.

THE PRACTITIONER AND THE VIRUS DIAGNOSTIC LABORATORY

JOSEPH E. SMADEL, M.D.
Washington, D. C.

Great advances have been made in the diagnosis, the control and the treatment of viral and rickettsial diseases in the last few years. They have resulted from intensive research carried out by laboratory workers, with the patient assistance of the practicing physician. The latter has been putting his time and effort into a long term investment which has now begun to pay dividends. My main object here is to advise him how to use his dividends wisely and how to avoid spending the principal unwittingly. I shall point out those methods which are now sufficiently well developed and standardized to be employed as routine diagnostic procedures. These every physician has a right to expect will be made available to him. In addition, I shall mention those procedures which are still so highly specialized that competent research workers are required for their satisfactory accomplishment. These research procedures are not the physician's to demand for use in routine diagnostic work. Rather they are the physician's to request only, and then in an investigation in which he cooperates with the laboratory worker. If the physician fails to employ these research procedures wisely, he is wasting the common investment in the advancement of medicine.

The isolation and the identification of viral and rickettsial agents are still research procedures. Let the physician recognize them as such and refrain from requesting them unless he is willing and able to cooperate in the investigation. In only a few instances will the isolation of the agents infectious for man provide useful information which could not have been obtained more quickly, easily and cheaply by serologic methods. It is not my purpose to present the technical details of laboratory procedures; for these, clinicians may consult their own laboratory specialists. I shall merely say that the recovery of a transmissible agent by inoculating animals with material suspected of containing it is difficult; furthermore, this is only the first step. The next step, identification of the agent, usually requires an elaborate organization and considerable time. At the Army Medical Department Research and Graduate School, which is completely equipped for such work, we consider ourselves fortunate if we are able to isolate and identify variola virus in three days and rabies virus in eight. There are more direct methods which will establish the diagnosis in less time. A minimum of ten days to three weeks is required, even under optimal conditions, for isolation and identification of such common viruses as those of lymphocytic choriomeningitis, influenza, psittacosis, St. Louis encephalitis and West-

ern and Eastern equine encephalitis, and of the Rickettsia of epidemic and murine typhus, spotted fever and rickettsialpox.

Such rapid identification of viral and rickettsial agents requires complete facilities for performing various serologic and cross immunity tests, and these in turn require the constant maintenance of a museum of infectious agents, as well as stocks of known antigens, antiserums and immune animals. In incompletely equipped laboratories the identification of a newly isolated virus awaits the acquisition of such materials, which must be prepared locally or procured from another laboratory. Before I leave the subject of isolation, let me reiterate that the advancement of knowledge requires that this method be used in order that new agents may be discovered, but it is not necessary for the diagnosis of most of the viral and rickettsial diseases of man, for which adequate serologic procedures have been developed. If isolation studies seem to be indicated, the clinician should consult his virus specialist as to the type of material which is to be obtained and how such material is to be shipped.

Serologic Tests for the Diagnosis of Common Viral and Rickettsial Diseases of Man in North America

† The day given is the first day on which an appreciable amount or e maximum level of antibody may be expected to be present.

There are satisfactory diagnostic serologic tests for number of the viral and rickettsial diseases occurring n the United States, and they should be available to ll physicians. The tests are listed in the table. The materials of a few of these are not difficult to prepare; owever, most of the diagnostic antigens require special acilities for their manufacture, but, once prepared, they re stable and noninfectious. The complement-fixing nd the agglutinating antigens required for the tests isted in the table are prepared at the Army Medical Department Research and Graduate School, and a number of them are supplied to Army laboratories throughout the world. Unfortunately, in some respects we are uthorized to serve military personnel only and cannot urnish the materials to nonmilitary laboratories. It is my firm conviction that these diagnostic antigens will be made generally available within a few years, for several commercial biologic houses have evinced an interest in the manufacture of such antigens. Their efforts should be encouraged, since the wide application of these diagnostic tests must await a ready supply of the antigens.

If one may assume that noninfectious viral and rickettsial antigens can be supplied freely, then all of the diagnostic procedures listed, except the neutralization tests for the encephalitides, could be performed in any hospital laboratory in which satisfactory Wassermann tests and bacterial agglutination tests are done. I know of no laboratories other than those of the Army Medical Department School and of the National Institute of Health which regularly perform all or even the majority of the tests listed. Several of the state and municipal laboratories provide some of the diagnostic procedures, and a number of laboratories associated with teaching institutions routinely perform a few of the tests. The delay in making these methods available to physicians is dependent on the nonavailability of the antigens.

It is not too difficult for a good hospital laboratory to run a few neutralization tests, but some special equipment and training are necessary. Neutralization tests are designed to detect protective antibodies and are performed by mixing the patient's serum with diluted virus and injecting the mixture into a susceptible animal. If obvious disease develops, this indicates that the serum contains no protective substances, while if the animal remains well, the serum does possess neutralizing antibody. Neutralization tests can be relatively simple and give useful diagnostic data. Virus workers harangue about the advantages of certain modifications of the technic, but most of their arguments belong in the category of the theologic question of how many angels can stand on the point of a needle.

The neutralization technic is listed in the table for the diagnosis of only three diseases, viz., the epidemic encephalitides of North America. These infections occur only in the summer and have a limited geographic distribution. Therefore, a laboratory serving a given area would be required to do only certain of these tests and then for only part of the year. Those situated along the Atlantic seaboard and the eastern coast of the Gulf of Mexico should make routine diagnostic tests for Eastern equine encephalitis but not for Western equine encephalitis or St. Louis encephalitis. Laboratories in the area bounded roughly by the Mississippi River, the Pacific coast and the Canadian and Mexican borders should perform tests for St. Louis encephalitis and Western equine encephalitis but not for Eastern equine encephalitis. There is one area, however, where all three should be done, namely, eastern Texas, Louisiana and Mississippi, for in this section all three agents are known to occur.

The serologic methods mentioned in the table represent only a portion of those which have been employed for diagnostic work. Thus, some modification of the Hirst agglutination inhibition test is used almost exclusively in the diagnosis of influenza, but neutralization and complement fixation technics were employed satisfactorily until the simpler Hirst method became available. In the diagnosis of lymphocytic choriomeningitis the neutralization test is extremely useful, while in diagnostic studies of St. Louis and Western equine encephalitis complement fixation technics have been employed. In the diagnosis of rickettsial diseases the results obtained with rickettsial agglutination tests are as valuable as those derived from complement fixation. The technics listed in the table have been selected for clinical use because they can supply the greatest amount of useful data with the smallest expenditure of money, equipment and personnel.

The various methods employed in the diagnosis of viral and rickettsial diseases were described in detail at a recent symposium, and the descriptions will soon be published in book form;[1] this material should be consulted for details and references.

The discussion so far has centered around those things which physicians may and should ask the laboratory man to do to assist them in their practice. Now I should like to devote a little time to the things they should do in order to obtain usable information from the diagnostic tests which they request. The physician should always aim to collect serum specimens in such a manner that a rise in antibody titer can be demonstrated during convalescence. He should always get at least two samples of serum from every patient suspected of having a diagnosable viral or rickettsial disease. The detection of specific antibodies is generally worthless if a single specimen of serum is examined in a neutralization test for encephalitis, a Hirst test for influenza or a complement fixation test for the psittacosis-lymphogranuloma group, or for mumps. The serums of too many persons contain these antibodies as a result of previous infections which may or may not have been recognized. Antibodies appear more quickly in some instances than in others. The early serum should be drawn before antibody has appeared or before a sharp rise of titer has occurred. The last day on which these conditions are met is given in the column in the table titled "Day of Bleeding—Early." The earliest day on which antibody can be expected to appear in appreciable amounts or to reach its maximal level is given in the column "Day of Bleeding—Late." It is not enough that the physician take the specimens at the proper times; he must also pass on this information to the laboratory man so that the latter can examine the material intelligently.

SUMMARY

Practical methods are now available for the diagnosis of many of the viral and rickettsial diseases which physicians encounter. These methods are not now generally available but will be as soon as the necessary special antigens can be supplied. The commercial manufacture of the antigens is the next step, which must be accomplished before these technics may be used extensively for the diagnosis of disease.

Rheumatism.--That rheumatoid arthritis may at times be a psychosomatic disease has been suggested, but most authorities agree that psychic disturbances alone cannot cause the disease. Grief, worry or anxiety may occasionally act as precipitating agents and in some cases appear to be temporally related to fluctuations in the clinical course of rheumatoid arthritis. But while emotional upsets may act as trigger mechanisms to set off the disease process, it is probable that the body must first harbor the causative factor (infectious agent or whatever the factor is).--Boland, E. W.: *California Medicine, April 1948*

ELECTRON MICROSCOPIC STUDY OF VIRUSES

RALPH W. G. WYCKOFF, Ph.D.
Bethesda, Md.

Electron microscopes make it possible to see the elementary infectious particles of the smallest viruses and thus to study these hitherto invisible agents of disease in the same general way that bacteria have been studied with optical microscopes. In such a study the first problem that arises, and one that must be successfully met before others can properly be attacked, involves learning to recognize the individual units of virus activity among the masses of tissue and other extraneous material with which they are associated. For this a virus should be available in purified form; otherwise, it is as dangerous to ascribe virus activity to specific objects seen in the microscope as it is to pick some particular organism in a mixed bacterial culture as being responsible for a disease induced by the culture as a whole. Viruses grow only on living matter, and they must therefore usually be separated from the large masses of host cells that have nurtured them. Research directed toward finding ways to do this will continue to be essential to a developing morphology of viruses.

Electron microscopy of purified suspensions has already provided accurate descriptions of the elementary particles of a number of viruses of plants and animals. Some have characteristic appearances that allow them to be recognized in crude infected tissue. Others, differing little in shape from normal constituents of healthy cells, may always remain hard to recognize in infected material.

The largest viruses have distinctive shapes. Some, like the poxes,[1b] are bricklike. The psittacine viruses—psittacosis, lymphogranuloma, feline pneumonitis and other members of this group—are less uniform in appearance.[2] Separate elementary bodies appear as collapsed spheres, but there are also present objects containing several spheres similar to the free bodies. Some bacteriophages are spermlike,[3] with heads that show characteristic internal structures and tails the appearance of which depends on the strain (fig. 1). Virus particles of the Newcastle disease of chickens are said [4] sometimes to have sheathlike appendages and sometimes to be without them. All the very small viruses of animals and most of the viruses of plants thus far photographed have spherical or nearly spherical particles. The virus [5] of rabbit papilloma and the less stable viruses of Eastern and Western encephalomyelitis [6] are of this sort. The virus of poliomyelitis also

has been reported[7] to be spherical as seen in purified extracts of diseased cord tissue.

The particles of many viruses of animals are not uniform in size; instead their diameters seem to be distributed, often widely, about a mean value. This variation in size is clearly evident in the influenza spheres[8] of figure 2. The elementary particles of all purified viruses of plants, on the other hand, show the sort of dimensional uniformity to be expected of chemical molecules. Thus the spherical particles of the bushy stunt virus[9] have diameters that are the same within the limit of measurement (fig. 3). Rods of the tobacco mosaic virus,[10] though often of different lengths in purified preparations, have a uniform diameter.

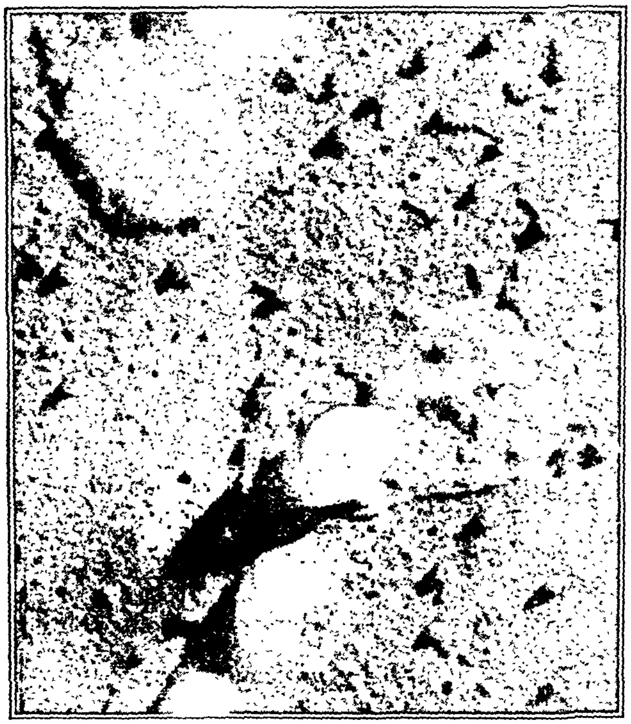

Fig. 1.—Strain T[4] bacteriophage particles among colon bacilli on the surface of an agar culture undergoing lysis. A collodion replica, chromium shadowed.

No virus of animals has yet been crystallized, and it is hard to imagine how pa[illegible]ze could arrange themselves into the [illegible], regular patterns that characterize a true crystal. Some viruses of plants, on the other hand, can easily be crystallized, and this is undoubtedly a consequence of the uniformity of their particles. Particles of uniform cross section but different lengths can pack with regularity in two but not in three dimensions. The tobacco mosaic virus forms such paracrystalline aggregates.[11] Plant viruses having spherical particles, on the other hand, form crystals in which their elementary bodies are as well arranged as are the molecules of other crystalline proteins. In favorable instances, the electron microscope reveals the exact details of this regularity[12] and thus provides a new and most direct method of determining crystal structure. Studies of these arrangements are already giving a precise insight into the basic phenomena of crystallization.

Once the morphologic characteristics of a virus are sufficiently understood, this understanding can serve as a basis for studying other of its important characteristics. Thus one can investigate by direct observation the products of reactions in which it takes part. The immune reaction that occurs between a virus and its specific antibody is undoubtedly one of the most important of these. Since individual molecules as small as those of the serum proteins can now be photographed, it has become feasible to examine this reaction down to its ultimate molecular level. This requires an antigen comparable in size with the antibody molecules; the smallest viruses approach this requirement. On the electron microscopic scale, the most striking evidence that a reaction occurs between a plant virus, for example, and its immune serum is the microagglutination[13] in which not more than a score of virus particles may be present in a single floc (fig. 4). The ability to observe a reaction involving such a fantastically small amount

of virus (of the order of a millionth of a millionth of a gram) suggests that extraordinarily sensitive diagnostic methods may be developed around the use of the electron microscope. Before this can be done, however, it is necessary to have an understanding of the reaction products formed by different antigens at a full range of antigen-antibody ratios. Studies that will result in this knowledge are also providing the basis for a thorough evaluation of current theories of the nature of the immune reaction and of the way serum neutralizes and affords protection against viruses and other proteins foreign to an animal.

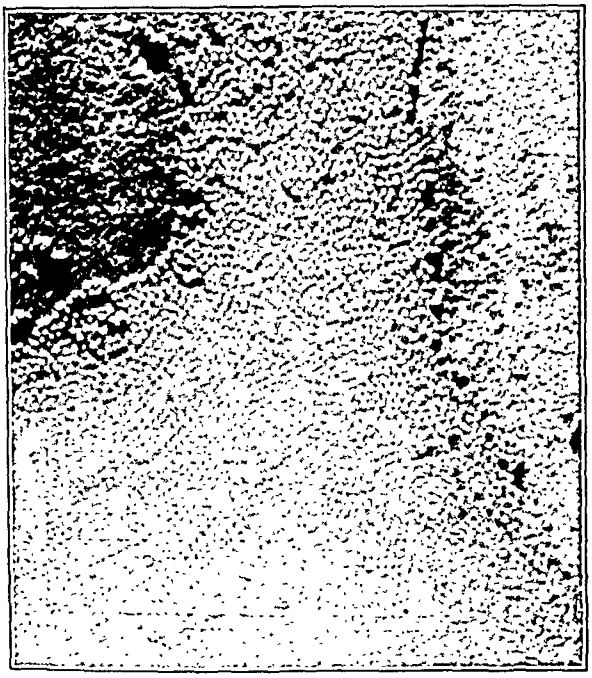

Fig. 3.—Masses of elementary particles on the edge of a desiccated droplet of a purified suspension of the bushy stunt virus. The beginnings of orderliness in particle arrangement, which results in crystal formation, are apparent. Gold shadowing; magnification, 38,000.

The ability to recognize virus particles by their characteristic sizes and shapes permits an approach to the extremely important and interesting problem of how they are produced or how they multiply. To do this it is necessary to work with viruses that are not in pure form but are within the cells which they infect. Ultimately this can be done by observing thin sections of cells in various stages of the virus infection. Sections suitable for electron microscopy must, however, be thinner than those that can be cut routinely with conventional microtomes. Special machines [14] having the high speed knives required to cut ultrathin sections are being developed, but much research in the technics of fixing and staining is needed to give them their full usefulness. A tissue can often be examined under the electron microscope without sectioning when it can be induced to grow in tissue culture as a single layer of cells.[15] This should be a fruitful way of studying the inclusion bodies produced by many viruses. The question of virus multiplication can also be approached by choosing host cells that grow singly rather than in a tissue and are small enough not to be opaque in the electron microscope. Bacteria and the bacteriophages that feed on them are probably the simplest systems of this sort. It is not hard to prepare replicas of such systems as they develop on the surface of an ordinary agar plate.[16] My associates and I have been studying the development of a number of bacteriophages in this way. The phenomena are of great complexity, depending, as they do, not merely on the organisms involved but also on their conditions of growth. Gradually, however, we are seeing the steps involved in the process by which a bacterium is converted into a mass of bacteriophage particles and are thereby gaining insight into the mechanism that brings it about.

Not all phages are sperm shaped as are those in figure 1, and they are not all found within the bodies of infected organisms. Often bacterial protoplasm will be almost completely transformed [17] into bacteriophage particles according to a pattern of practically crystalline regularity. We are gradually perceiving the implications of such observations for the nature of bacteriophage. With certain systems, lysis leaves behind such diverse particles that it is hard to be certain which of them carries the activity. This is the case for instance with Proteus bacilli, whose plaque areas are rich in multiply flagellated objects. Are these objects carriers of bacteriophage activity and are they perhaps motile "living" objects, too small to be visible in anything but the electron microscope? Information about these and many other novel questions raised by venturing into this hitherto impenetrable world of small objects is important not only to an understanding of viruses and the diseases they produce but to the most basic questions dealing with the nature of the living process itself.

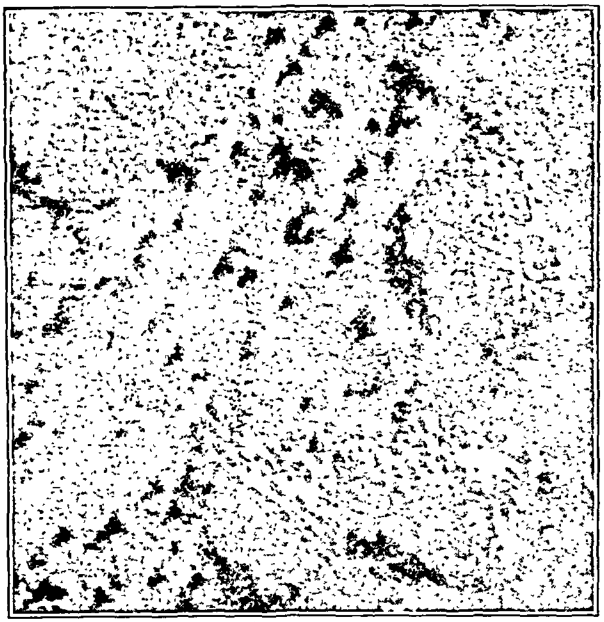

Fig. 4. Several microflocs of bushy stunt virus agglutinated specifically by antiviral rabbit serum. The disordered array of the virus particles in a floc is to be compared with their partially ordered arrangement in such a deposit of pure particles as that shown in figure 3. A gold shadowed replica; magnification, 43,000.

COMMON VIRUS INFECTIONS OF THE RESPIRATORY TRACT

DIAGNOSIS AND ETIOLOGY

JOHN H. DINGLE, M.D.
Cleveland

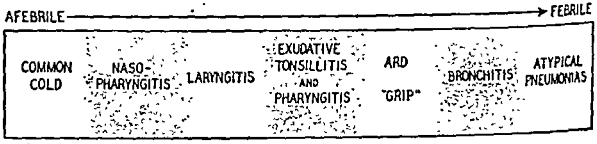
Knowledge of certain virus infections of the respiratory tract has increased greatly within the short span of the last fifteen years. During this period two distinct types of influenza virus have been isolated and characterized,[1] the large group of immunologically related viruses termed the "psittacosis-lymphogranuloma" group has been more sharply delineated,[2] and important advances have been made in the understanding of contagious diseases, such as measles [3] and mumps,[4] which are due to viruses and are spread by secretions of the respiratory tract. These well known specific infections, however, together comprise the lesser part of the problem of virus infections of the respiratory tract.

The greater part of the problem, in terms of frequency of occurrence of cases,[5] encompasses the group of common infections which vary in their clinical characteristics from the "common cold" to the "atypical pneumonia" and are referred to by a variety of additional names, including "nasopharyngitis," "laryngitis," "grip," "common respiratory disease," "catarrhal fever," "tracheitis" and "bronchitis." A great deal of time and effort have been devoted to investigations of this group of infections, but relatively little is yet known about their interrelationships and causation. While some of the infections have been found to be due to filterable agents, presumably viruses,[6] no one of the agents has been isolated and cultivated in the laboratory in a manner which permits adequate characterization.

Much has been written about diseases of the respiratory tract due to the viruses of influenza, psittacosis and other well characterized agents. It is the purpose of this paper to consider the present status of the diagnosis and etiology of those common infections whose differentiation and classification are as yet ill defined.

GENERAL CONSIDERATIONS

From the standpoint of clinical diagnosis the various common forms of mild infection of the respiratory tract present a major problem, both with respect to segregating them as a group from those due to known specific viruses and bacteria, and with regard to separating, one from another, the possible entities within the group. In part at least, this difficulty arises from the relatively limited capacity of tissues of the respiratory tract to react to the presence of any noxious agent. While single or multiple symptoms and signs may be almost pathognomonic for infection with a few known agents, the clinical picture in the majority of patients is dependent on nonspecific features, such as congestion, edema, altered secretory activity of the mucosal cells, leukocytic infiltration and, in some instances, necrosis and formation of a membrane. In addition, the constitutional reactions of fever, chilliness or rigor, aching, and malaise may have varying degrees of prominence. Thus the clinical picture depends on which of these features are predominant. More than one agent may produce the same clinical type of illness, and, in addition, a single agent, such as influenza virus A, may induce diverse clinical pictures simulating almost any of the common diseases of the respiratory tract.[7]



Spectrum of common respiratory diseases. *ARD* signifies "acute respiratory disease."

It is apparent, therefore, that the diagnosis of any of the common undifferentiated infections of the respiratory tract can now be made with certainty only by the exclusion of diseases of known cause, such as tuberculosis, diphtheria, beta hemolytic streptococcus infections, influenza and psittacosis. When such exclusion has been carried out, there remain a large number of cases which can be grouped in a "clinical spectrum" according to the predominant features of the cases (figure). Obviously, this arrangement is an artificial one based on fever and other factors contributing to severity of illness, on the anatomic location of the principal symptoms and signs and, in one instance, on a single sign—exudate—present on the tonsils or the pharyngeal wall. It is impossible to draw sharp lines between these groups, which clinically shade into one another and vary within themselves. Such a classification, however, does provide a means of selecting cases by clinical criteria for the study of causation and the separation of etiologic entities. While not all of the groups named have been investigated sufficiently to warrant more than the foregoing mention, evidence is now available which suggests that four of these categories may represent separate etiologic entities, namely, the "common cold," nonbacterial exudative pharyngitis

and tonsillitis, "acute respiratory disease" (*ARD*) and primary atypical pneumonia.

"COMMON COLD"

The "common cold" is usually defined as a mild, self-limited, afebrile respiratory illness, characterized by catarrhal inflammation of the mucous membranes of the nose, the sinuses and contiguous structures of the upper respiratory passages. The prominent features diagnostically are coryza, lacrimation, a dry and scratchy throat, an irritative cough, swollen and congested nasal mucous membranes and a normal leukocyte count. But considerable clinical variations are seen in "colds" as they occur in different persons and in the same person at different times. Some appear to be localized in the nose and the sinuses, or the throat; others, regardless of the area of initial involvement, spread to affect almost the entire respiratory tract. Some are mild, without systemic reactions; others are more severe, with associated fever, chilliness, malaise and other constitutional symptoms. Clinically, then, the diagnosis of "common cold" encompasses. illnesses which may represent variations of a single disease entity or which may be due to multiple agents.

The investigations of Kruse, Foster, Dochez, Long and their respective co-workers [6a-d] demonstrated that coryzal types of illness with a short period of incubation could be transmitted to well human beings and chimpanzees by inoculation of bacteria-free washings of the respiratory tracts of patients with "colds." Recent investigations of the Commission on Acute Respiratory Diseases [6e, f] have confirmed and extended these studies. Mild, afebrile coryzal infections of the upper respiratory tract were induced in volunteers by inoculation of bacteria-free filtrates of throat washings from each of two donor subjects. One of these donors experienced a moderately severe illness—termed a "severe common cold"—characterized by low grade fever, sneezing, profuse coryza, productive cough and the constitutional symptoms of feverishness, headache, malaise and anorexia. The nasal mucous membranes were injected and edematous, and there was mild hypertrophy of the pharyngeal lymphoid follicles. No abnormal signs were present in the chest. The lungs and the sinuses appeared to be normal on roentgenographic examination. Leukocyte counts were 11,800 and 9,700 on the second and the fifth day, respectively. Cultures of pharyngeal material and sputum revealed no significant pathogenic bacteria. The duration of illness was sixteen days. The other donor suffered a mild illness, without fever, but with dryness and irritation of the throat, nasal obstruction and discharge, sneezing, hoarseness and a dry cough. Physical examination revealed only congestion and edema of the nasal mucous membranes. Roentgenographic examination of the lungs and the sinuses, and other laboratory studies revealed no abnormalities. The illness lasted approximately five days and was termed a "common cold."

Mild, afebrile illnesses, characterized principally by sneezing, coryza and nasal obstruction, were produced in approximately two thirds of each group of volunteers inoculated with filtered washings from these two donors. Symptoms developed within twenty-four to forty-eight hours after administration of the inoculums. Physical examination revealed injection and swelling of the nasal mucous membranes, associated with nasal discharge. Despite the differing clinical characteristics of the illnesses in the two donors, there were no recognizable differences in the infections induced by the respective inoculums. Repeated cultures of material taken from the throats of the recipients before and after inoculations showed no unusual changes in the character of the bacterial flora. The duration of the illnesses was approximately seven to ten days in each group.

As a control, each of a group of 9 men was inoculated with an autogenous washing, similarly collected and filtered. In none of these men did any symptoms or signs of infection develop during the following thirty days. It was therefore concluded that the procedure of inoculation was not in itself responsible for the results obtained.

In an attempt to define further the nature of the infections induced by the "common cold" inoculums, certain of the volunteers were reinoculated with the same or with homologous filtrate after an interval of approximately three weeks. Coryzal illnesses again developed within twenty-four to forty-eight hours, indicating the absence of active immunity under these conditions of exposure. A lack of heterologous immunity also was shown by the occurrence of illnesses following subsequent inoculations made in these men at successive intervals with two heterologous washings obtained in cases of "acute respiratory disease" and primary atypical pneumonia.

It would therefore appear that coryzal illnesses resembling the "common cold" and having an incubation period of one to two days can be transmitted to human subjects by the administration of filtered secretions of the respiratory tracts of patients whose clinical illnesses differ at least in severity, if not in other respects. Presumably the causative agents are viruses. Further investigations are necessary to determine whether or not single or multiple agents are involved, to evaluate more fully the apparent lack of active immunity and to develop specific diagnostic tests.

NONBACTERIAL EXUDATIVE TONSILLITIS AND PHARYNGITIS

The occurrence of cases of nonbacterial exudative tonsillitis and pharyngitis has been observed by a number of investigators,[8] particularly in geographic areas having a relatively low incidence of beta hemolytic streptococcus infections. In certain studies [8c-f] the frequency of occurrence of respiratory illnesses associated with pharyngeal or tonsillar exudate not attributable to bacteria has been three times as great as that of illnesses due to streptococci or other bacteria.

Nonbacterial exudative tonsillitis and pharyngitis is generally a mild disease of short duration. The onset is ordinarily gradual, and the early complaints of the majority of patients are those of feverishness, headache and anorexia. Symptoms of sore throat, hoarseness and cough, often productive, are noted by

75 per cent or more of the patients and tend to reach great prevalence by the third or fourth day of illness. Nasal symptoms are not prominent. On physical examination the mucous membranes of palate, pharyngeal wall and tonsils show varying degrees of injection, which usually is not severe. The exudate is ordinarily small in amount and appears as gray or yellow individual spots which are pinhead in size. Larger patches of exudate may develop, but rarely do they become confluent. Often the exudate forms over swollen lymphoid follicles on the pharyngeal wall. Cervical lymphadenopathy may be present in approximately one fourth of the cases. Involvement of the lungs occasionally occurs.[9] In approximately two thirds of the cases the total leukocyte counts are below 10,000 and the differential formulas are normal. Bacteriologic and serologic examinations give no evidence of beta hemolytic streptococcus infection. The average peak of temperature is between 101 and 102 F, and the fever ordinarily declines by lysis. The duration of illness is approximately five days, and convalescence is usually uneventful.

The cause of this syndrome has not been determined, nor have direct attempts been made to transmit the infection in man. It is worth mention, however, that in the experimental transmission of primary atypical pneumonia and minor respiratory illness to human volunteers, pharyngeal or tonsillar exudate of minimal degree was present in 2 cases of pneumonia and in 2 cases of minor illness.[10] Whether a single agent or more than one agent was active in these cases cannot be determined, however, because the particular inoculum given these persons was not filtered and consisted of specimens pooled from several donors. At the present time the disease can be diagnosed only after the exclusion, by cultural and serologic methods, of the common bacterial infections. While it is recognized that exudate is not necessarily pathognomic of a specific infection, a brief description of the syndrome of nonbacterial exudative tonsillitis and pharyngitis has been presented here because this condition may represent an etiologic entity among the common virus infections of the respiratory tract.

"UNDIFFERENTIATED ACUTE RESPIRATORY DISEASE"

It has long been common knowledge in military circles that recruits are highly susceptible to disease of the respiratory tract during their first few weeks of training. Experiences of the past war have confirmed this observation [11] and, in addition, have shown that the bulk of those illnesses which require hospitalization appear to represent an epidemiologic and clinical entity which for lack of a better term has been called "undifferentiated acute respiratory disease" by the Commission on Acute Respiratory Diseases.[11b] Epidemiologically this type of illness has shown a constant pattern of behavior during three years of observations. Epidemics have occurred in recruits with regularity during the winter months.[11b] Clinically the diagnosis has been made by the exclusion of bacterial infections, influenza A and B, exudative lesions of pharynx or tonsils, and pneumonia. While this syndrome has been recognized in military populations, there is no reason to believe that it does not also occur in civilians.[8a,b]

The clinical picture of "undifferentiated acute respiratory disease," as seen in hospitalized recruits is that of a mild respiratory illness of gradual onset. The most frequent complaints are those of feverishness, chilliness and headache. Symptoms of malaise, anorexia and nasal involvement occur in approximately half of the patients. Sore throat is common but is mild in degree in comparison with that encountered in patients having exudate in the throat. Minimal hoarseness and cough are common, although fewer than half of the patients have a productive cough or pain in the chest. On physical examination the patients rarely appear to be severely or even moderately ill. Physical signs are remarkably few and are usually noted in less than half of the patients. Nasal obstruction, mild injection of pharynx and palate, and lymphoid hyperplasia on the pharyngeal wall are most frequently found. Edema of the mucous membranes, cervical adenopathy and thoracic rales are present in approximately 10 per cent of the patients. The febrile course is short, from two to four days, and the average maximum temperature is about 101 F. Constitutional symptoms subside with defervescence, but symptoms referable to the respiratory tract, when present, tend to persist for one or two weeks. Leukocyte counts are usually within normal limits, and cultures of the throat reveal only normal bacterial flora.

It therefore appears that the syndrome of "undifferentiated acute respiratory disease" may be a clinical entity of nonbacterial origin, which differs from the "common cold" or acute coryza. Attempts to isolate the causative agent in animals have been unsuccessful. Mild respiratory illnesses have been transmitted to human volunteers, however, by means of filtered throat washings from a representative donor.[6e,f] Fourteen of 19 men inoculated became ill, and in 10 of the 14 patients symptoms first appeared on the fifth or sixth day after inoculation. While the clinical pattern was somewhat variable, the initial complaints were usually those of dryness or soreness of the throat which developed gradually during the course of twenty-four or forty-eight hours. Constitutional symptoms were minimal or absent; nasal symptoms were of minimal intensity and not associated with coryza. Mild inflammation of palate and pharynx and lymphoid hyperplasia were the only noteworthy signs on physical examination. The course of illness in general was mild and afebrile, and the duration of symptoms varied from four to twelve days. Laboratory studies yielded normal results.

Reinoculation of 6 of these men with filtered washings from the same donor produced no illness. It thus appeared that "undifferentiated acute respiratory disease," in contrast with the "common cold," was followed by homologous active immunity. Successive inoculations of these men, at later periods, with filtrates of throat washings from the patient with "severe common cold" and from a patient with primary atypical pneumonia, however, failed to demonstrate heterologous immunity to the agents producing the latter two types of respiratory disease.

This study in human volunteers indicates that a mild disease of the respiratory tract characterized by an incubation period of five to six days and predominance of pharyngeal symptoms and signs can be transmitted in man. The disease not only has a longer period of incubation than the "common cold" but also appears to be immunologically distinct. The causative agent is filterable and is presumed to be a virus. The evidence now available suggests that this experimentally induced illness is the same as the "undifferentiated acute respiratory disease" of recruits, but final acceptance of this relationship must await isolation of the virus and the development of specific serologic tests for confirmation of the diagnosis.

PRIMARY ATYPICAL PNEUMONIA

Within the past ten years primary atypical pneumonia has become the commonest form of pneumonia, in terms of frequency of occurrence, and has been the subject of numerous reports and reviews.[12] Only limited consideration, therefore, will be given here to its diagnosis and etiology.

Primary atypical pneumonia is an acute disease of the respiratory tract or a syndrome characterized chiefly by gradual onset, benign course and diffuse or patchy pulmonary infiltration demonstrable by roentgenogram. In some patients the constitutional symptoms of headache, feverishness, chilliness, malaise and fatigue are prominent in the early stages of illness and gradually increase in severity. In others, the illness begins as a localized infection of the respiratory tract, as indicated by dryness and soreness of the throat and by cough, and constitutional symptoms develop either simultaneously or after several days of illness. Coryza may be noted in about one third of the cases. As the disease progresses, the cough ordinarily becomes productive of greenish yellow mucopurulent sputum. Rarely is the sputum intimately mixed with blood. Substernal pain of a dull character commonly accompanies the cough. Physical examination early in the illness usually reveals little beyond mild infection of the pharynx. Later, however, medium fine, sticky rales and coarse rales are characteristically heard over the involved area of the lungs. The classic signs of consolidation—dulness, increased tactile fremitus and altered breath and voice sounds—are rarely observed.

Roentgenographic examination frequently provides the first evidence of pulmonary involvement. The infiltration is usually light and patchy in character and peribronchial in distribution, compatible with the pathologic changes of interstitial pneumonia, lobular atelectasis and necrotizing bronchiolitis. The process may begin at the hilus or in the parenchyma of the lung. The lower lobes are most frequently involved, but any portion of the lung may be affected. In general, diffuse involvement, particularly of the upper lobes, is found in the more severely ill patients.

The usual clinical laboratory examinations yield results which are within normal limits. The total leukocyte count is ordinarily less than 10,000, and the differential formula is normal. Urinary changes, if present, are those compatible with any febrile illness. Cultures of the sputum and of the throat show the normal occurrence and distribution of the bacterial flora of the respiratory tract.

The course of the average illness is benign and of approximately five to seven days' duration. Complications are infrequent, and the prognosis is excellent, despite the lack of specific therapy.

Thus, the characteristics of primary atypical pneumonia are such that a definite diagnosis may at times be extremely difficult if not impossible to establish on the clinical features alone. It may be necessary to exclude, by the appropriate diagnostic procedures, a number of diseases of known cause which may present essentially the same syndrome, such as tuberculosis, tularemia, bacterial pneumonia, coccidioidomycosis, Q fever, psittacosis and influenza.

While the diagnosis of primary atypical pneumonia is still one of exclusion, two laboratory tests are of some help. Both of these tests are agglutination reactions in which acute and convalescent phase specimens of the patient's serum should be examined in order to demonstrate a rise in antibody titer. The first or "cold hemagglutination" test[13] utilizes group O human red blood cells as antigen, and the reaction occurs only at a cold (usually icebox) temperature. On warming to 37 C. the hemagglutinin disappears. The second test is the agglutination of Streptococcus MG[14] and is carried out in essentially the same fashion as other bacterial agglutination tests. The proportion of patients whose serums show significant increases in titer for one or the other of these agglutinating antibodies or for both has varied in the several reported series of cases, but, in general, approximately 50 per cent of the patients show development of the antibodies.[12e] The two reactions appear to be directly correlated with severity of illness and extent of pulmonary involvement. It should be emphasized that each test provides only a restrospective confirmation of the diagnosis of primary atypical pneumonia, since the antibodies do not develop until the second or third week of illness. Moreover, failure to demonstrate the antibodies does not exclude the diagnosis.

The causation of primary atypical pneumonia was extensively investigated in a number of laboratories during the war. Attempts to establish in animals an infection which could be related immunologically to the human disease have for the most part been unsuccessful.[15] Eaton and his co-workers,[16] however, have reported that pulmonary lesions were produced in cotton rats and hamsters by intranasal administration of bacteria-free suspensions prepared from chick embryos previously inoculated with specimens from patients with primary atypical pneumonia. That the agent is neutralized by convalescent serums has been reported in approximately 60 per cent of cases of primary atypical pneumonia and 20 per cent of cases of the undifferentiated infection of the upper respiratory tract.[16b]

J. Hyg. **45**: 82-95 (Jan.) 1947.

Studies of the Commission on Acute Respiratory Diseases[10] have demonstrated that primary atypical pneumonia can be transmitted to and passed in human volunteers by means of bacteria-free filtrates of sputum and throat washings. In approximately one fourth of the volunteers respiratory illnesses developed, with pulmonary infiltration being demonstrated roentgenographically. Clinically the experimentally induced infections resembled the naturally acquired disease. The average period of incubation was ten to twelve days. There was no evidence that bacteria played any part in initiating the infections or during the course of the disease.

The clinical and the experimental evidence thus indicate that primary atypical pneumonia is a virus infection of the respiratory tract. Further investigation is necessary, however, to determine whether or not one agent or more than one is concerned in the production of the naturally acquired disease.

CONCLUSIONS

In conclusion, the outstanding problem in the field of diseases of the respiratory tract relates to the common infections of the respiratory tract which are so frequent in occurrence and which appear to vary in type from the "common cold" at one extreme to "atypical pneumonia" at the other. These infections are thought to be caused by viruses as yet uncharacterized, but they may be segregated into a group at the present time only by the exclusion of cases due to the known bacteria and viruses: Clinical classification is unsatisfactory at best, since it is based mainly on severity, extent of involvement of the respiratory tract and prominence of localizing symptoms and signs. An attempt at differentiation, however, has been useful as a means of selecting cases for etiologic investigation. It now appears probable that three entities, termed the "common cold," "undifferentiated acute respiratory disease" and "primary atypical pneumonia," can be separated from the larger group. Each of them can be transmitted to well human beings by the inoculation of bacteria-free filtrates of secretions of the respiratory tract. The possible existence of a fourth entity, "nonbacterial exudative tonsillitis and pharyngitis," is indicated by clinical studies.

The Campaign Against Rheumatism.—In every country surveyed the same findings have been made: (1) rheumatic diseases outranked all others as a cause of chronic morbidity; (2) rheumatic diseases annually involve each country in great expense; (3) adequate facilities for the care of most rheumatic patients are nonexistent. In the United States as elsewhere the total army of rheumatic victims is relatively neglected. Compare their prospects with that of others, for example, the tuberculous: for our 680,000 tuberculous patients there are available about 100,000 free beds and $100,000,000 for care and research. But for our 6,850,000 rheumatic patients there are available only about 200 free beds and $200,000 for care and research. In other words, although there are 10 times as many rheumatic as tuberculous patients the latter have available 500 times more beds and money. Thus the tuberculous patient, happily thereby a "vanishing race," receives 5,000 times as much attention as the nonvanishing rheumatic.—Hench, P.S.: *Annals of Internal Medicine*, February, 1948.

SEARCH FOR EXTRAHUMAN SOURCES OF POLIOMYELITIS VIRUS

THOMAS FRANCIS Jr., M.D.
GORDON C. BROWN, Sc.D.
and
LAWRENCE R. PENNER, Ph.D.
Ann Arbor, Mich.

The best evidence of the transmission of the virus of poliomyelitis at the present time supports a person to person transfer. In spite of the logic of this thesis, based essentially on the well known fact that virus is present in the human oropharynx and intestinal tract for varying periods, one must not forget that the evidence was arrived at through processes of elimination rather than by scientifically proved experiments. Consequently, it is difficult, if not impossible, in determining the transmission of this disease, to rule out extrahuman factors completely, especially since epidemiologic observations have emphasized for years that outbreaks of poliomyelitis are correlated with seasonal influences, such as rainfall, temperature and prevalence of insects and animals.

In reviewing the literature on this subject one is impressed by the vast number of incriminations of various extrahuman factors, based at best on epidemiologic impressions gained through observations of limited accuracy, and also by the paucity of reports, either positive or negative, in which it is indicated that confirmation has been sought through actual investigation. Thus, the value to other investigators of the reporting of negative results is emphasized by the fact that so few reports on this subject exist.

Milk has been condemned in several epidemics, but entirely without laboratory support. Neustaedter and Thro[1] reported that poliomyelitis developed in monkeys infected with dust from a sickroom. Kling[2] and Toomey and his co-workers[3] seem to be the only ones reporting that the virus of poliomyelitis has been isolated from water. Sewage is not truly extrahuman, since it represents human excreta which may contain virus. Virus has actually been found in sewage by Paul, Trask and associates,[4] by Toomey[5] and by Kling and associates.[6] These isolations were almost invariably made from samples taken near the source of outlet and not far from hospitals containing patients with poliomyelitis. Jungeblut

and associates[7] have reported that rodent-paralyzing agents were isolated from wild mice in several different areas, but considerable doubt exists as to the identity of these strains as agents associated with the human disease. Leake[8] attempted to recover the virus from stools of dogs and chickens, with negative results, as did Toomey and associates,[9a] who also failed to isolate the virus from fish.[9] That the antibodies are present in the serum of animals has been reported by Hammon,[10] Gordon,[11] Brown and Francis[12] and others, but it is significant that the serums were tested against only the mouse-adapted Lansing strain of poliomyelitis virus. The significance of these observations in terms of specific virus effect is not established.

The possibility that some insect plays a role in the transmission remains the most likely of all the extrahuman prospects. Rosenau and Brues[13] and Anderson and Frost[14] reported experimental transmission with the biting fly, Stomoxys calcitrans, but were unable to repeat their results a year later.[15] Sawyer and Herms[16] likewise were unsuccessful with this insect, as was Francis[17] with another biting fly, Lyperosia irritans. Howard and Clark[18] reported negative results of experiments with mosquitoes and lice, and Kling and Levaditi[19] found that flies and bedbugs were negative for virus. Simmons, Kelser and Cornell[20] and Cornell and Davis[21] were unable to transmit infection from monkey to monkey with the mosquitoes Aedes aegypti and Culex pipiens.

Flexner and Clark[22] and Howard and Clark[18] reported that monkey cord virus survived in the housefly, Musca domestica, for several days. Bang and Glaser[23] found that the Lansing strain of virus persisted in the housefly for two days but not in species of Lucilia, Muscina, Calliphora or Sarcophaga. The housefly yielded a strain of spontaneous mouse encephalomyelitis virus twelve days after feeding on the virus. The virus was not isolated from adults when the larvae were infected. Rendtorff and Francis[24] also reported that the Lansing strain was recovered from houseflies as long as two days after a single meal of virus but observed a marked decrease of this virus with time, indicating no multiplication of the agent. The virus was shown to be in the fly and to be excreted in the fecal and vomit spots.

Various workers have recently reported that the virus of poliomyelitis was isolated from captured wild flies—Paul and associates,[25] Toomey and co-workers,[26] Sabin and Ward[27] and Trask and associates.[28] A significant observation was reported by Ward, Melnick and Horstmann,[29] who exposed food to flies in an epidemic area and then fed it to chimpanzees. In these animals infection developed without clinical disease but with persistence of the virus in the gastrointestinal tract.[30]

In this laboratory, in the course of investigating epidemics of poliomyelitis during the past five years, attempts have been made to evaluate the significance of some of the possible extrahuman sources of virus. The efforts to be reported here represent attempts to isolate the virus from various materials, serologic studies to detect antibodies for the virus of poliomyelitis in animals and laboratory experiments with insects.

ATTEMPTS TO ISOLATE THE VIRUS

Mice.—Six pools of mice, representing 33 animals, have been tested for the presence of virus. The mice were captured in or near the homes of patients in three epidemic areas, Michigan, in 1942,[31] and Fort Worth and Texarkana, Texas, in 1943.[32] One animal appeared to be paralyzed. Nervous tissue and several inches of the lower part of the intestine were ground with alundum and filtered through Mandler candles. The bacteriologically sterile filtrates were inoculated intracerebrally in rhesus monkeys, white Swiss mice and cotton rats. No specimen produced signs of the disease.

Rats.—The nervous and intestinal tissues of 112 wild rats, rattus norvegicus, have been tested.[33] The animals were obtained from epidemic areas in rural districts of Michigan, in Texas and in Buffalo and Detroit. Mandler filtrates of 35 pools representing the total number of rats were inoculated intracerebrally in rhesus monkeys, Swiss mice and cotton rats. All specimens failed to transmit infection, with the exception of one pool of brains, cords and intestines from rats captured at the city dump in Fort Worth, Texas, in 1943.[32] A Mandler filtrate of the ground tissues from these animals produced paralysis in 1 of 2 cotton rats on the ninth day and in 1 of 6 mice on the thirtieth day. A rhesus monkey inoculated intracerebrally with the same original suspension had marked weakness of both legs and slight weakness of both arms by the ninth day. On autopsy of this animal some neuronophagia and neuronolysis was observed, but an attempt to pass the infection to a second monkey was unsuccessful. The brain and cord of the paralyzed mouse was passed to 4 cotton rats and 10 mice. Paralysis developed again in 1 cotton rat, but further passage was unsuccessful. However, the agent was passed in 9 successive mouse inoculations, inciting typical hind- or foreleg paralysis in the animals. Unfortunately, the percentage of mice in which paralysis developed never exceeded 20 to 25, making it impossible to identify the agent by means of the technic of cross immunization or cross neutralization. The strain has been preserved, and further attempts are being made.

Muskrats.—Three muskrats inhabiting the waters of Three Rivers, Mich., during the epidemic of 1946 were trapped. The rivers in this area were excessively contaminated with fecal material since they received raw sewage from the entire town. The pooled brains and cords and individual suspensions of the intestines of these animals were inoculated intracerebrally in 2 cotton rats and 15 white mice. No signs were observed in the test animals.

Chickens.—Chicken droppings were collected in two epidemic areas of rural Michigan,[31] and in Fort Worth, Texas,[32] where chickens represented the major animal species apart from man. Four pools were rendered bacteriologically sterile and were then inoculated intracerebrally and intranasally in rhesus monkeys. All pools failed to produce signs of virus infection.

On four occasions chickens which were limping or were totally unable to walk were observed in yards of homes where poliomyelitis was occurring. Histories revealed that several other chickens had recently died after being lame for a period. The brains and spinal cords were removed aseptically, ground in a mortar and inoculated intracerebrally in white mice. In none of these mice did signs develop.

Cows.—Seven pools of cow feces, representing four epidemic areas, three in Michigan and one in Texas,[34] were processed for intracerebral and intranasal inoculation of rhesus monkeys. One of the cows had a history of recent lameness. All specimens failed to produce signs of virus infection.

Hogs.—Droppings from hogs which were maintained by households in which the disease occurred were collected on two occasions.[31a] Four pools of ether-treated feces were inoculated intracerebrally and intranasally in rhesus monkeys, with negative results.

* The abbreviations are as follows: i.p., intraperitoneal; i.n., intranasal; i.c., intracerebral:

† A negative sign means that the inoculated animals showed no *evidence of virus infection; a plus sign, that definite symptoms of polio*myelitis developed after inoculation.

---

[34] Pearson and Rendtorff.[31] Pearson and others.[33]

Horse.—The stool of a horse which had been in close contact with a patient [31a] was tested for virus by intracerebral and intranasal inoculation of a rhesus monkey. No virus was detected.

Cats.—An interesting set of circumstances surrounded a group of three houses on the outskirts of Buffalo during the epidemic of 1944, where observations were being made by Dr. E. M. Bridge and Dr. E. Neter. In the three houses there occurred 1 definite case of poliomyelitis and 3 cases of minor illness which may have been abortive poliomyelitis. Two children had recently visited the homes; in one definite symptoms developed, and in the other, probably the abortive form of the disease. Of 13 cats residing in these homes, 9 had died within the past few weeks, 3 were well and 1 had flaccid paralysis of the legs. Through the cooperation and assistance of Drs. Bridge and Neter, these 4 remaining animals were killed, and the nervous tissue was removed and sent to us; it was then stored in dry ice until tested by intracerebral and intraperitoneal inoculation in a rhesus monkey. The animal remained perfectly well for the test period of thirty days.

Sewage.—Six specimens of sewage, 5 gallon (19 liter) quantities, were obtained in Fort Worth, Texas, during the epidemic of 1943.[32] A sample of raw sewage, a sample of the final effluent and 4 samples representing various areas of the town were chosen. Each sample was concentrated to a volume of approximately 1 quart (1 liter) by lowering the p_H to 4.2 and precipitating with crystalline egg albumin. The concentrates were preserved by freezing until tested. From 100 to 125 cc. of each was treated with ether to remove the bacteria and then inoculated at least twice in rhesus monkeys intraperitoneally and intranasally in 10 cc. and 2 cc quantities, respectively. The specimen from raw sewage was tested in 3 animals. All were negative for virus.

During the epidemic in Denver, 1946, six daily 1 quart samples of sewage were taken from three sources, the hospital outlet, the stream before it entered the treatment plant and the final effluent.[35] Two hundred cubic centimeters of each daily specimen from each location was used for a pool totaling 1,200 cc., which was then concentrated *in vacuo* to 40 cc. After ether treatment, each of the three pools was inoculated twice intracerebrally in 3 rhesus monkeys. All 3 pools gave negative results.

A pool of soil, totaling 80 Gm., from three truck farms irrigated by the Platte River, which contains the final effluent of the entire city of Denver, was suspended to 10 per cent in distilled water and concentrated *in vacuo*. After treatment with ether, the pool was inoculated intracerebrally in 3 rhesus monkeys, which remained well.

Since sludge from the sewage treatment plant is used extensively as fertilizer in and around Minneapolis, 2 specimens were obtained during the epidemic of 1946. A specimen of three year old sludge, which is usually used on farms, and a specimen of fresh sludge, 40 Gm. of each, were suspended in saline solution and treated with ether. Both were inoculated intracerebrally and intraperitoneally in Philippine monkeys. The animals remained well.

Water.—Nine large samples of water, usually several gallons each, were collected from lakes, ponds, rivers and city water supplies near epidemic areas in Cleveland, Akron, Ohio, Fort Worth, Texas, and several small towns of Michigan.[36] Each specimen was evaporated in sausage casings exposed to electric fans until concentrated to approximately 10 per cent of the original volume and then was inoculated intraperitoneally and intranasally in rhesus monkeys. In 2 monkeys symptoms suggesting infection developed, but the second rhesus passage was uneventful. The other inoculations produced no evidence of infection.

One 15 gallon (56 liter) specimen from the wells of the Perrysburg, Ohio, water department was collected over a twenty-four hour period during the epidemic of 1944. The specimen was concentrated *in vacuo* to a volume of 1 liter, while being maintained at a temperature of 40 F. and a p_H between 6 and 7. It was dialyzed and inoculated intracerebrally in white mice and 3 rhesus monkeys. No virus was recovered.

Milk.—Three specimens of raw milk from farms on which poliomyelitis had occurred [31a] were treated with ether and inoculated intracerebrally and intraperitoneally in rhesus monkeys. All the animals remained free of disease.

Insects.—Forty-three pools of insects, representing approximately 15,300 individual insects, trapped in areas under study,[34] have been tested in monkeys. Two pools of ants and two of cockroaches, with estimated numbers of 6,000 and 140, respectively, were obtained from each of two homes in which cases had occurred. A pool of ticks was made up of larvae, nymphs and adults numbering 150 obtained from a woody area frequented by a patient. Thirty-eight pools, representing seven epidemic areas, were made up of flies trapped in or around the residences of persons suffering with the disease. Many pools were made up of single species of flies. In some instances several kinds were included. In all cases the pools were ground in mortars with alundum, shaken with ether for several days and then, if bacteriologically sterile, inoculated intracerebrally as well as intraperitoneally or intranasally in monkeys.

Java, Capuchin, rhesus or Philippine monkeys were employed, and 10 pools were injected into both rhesus and Philippine monkeys. Table 1 demonstrates the results of these tests. It will be seen that, of all the pools of naturally caught flies, only one specimen, consisting of 23 flies from an unsanitary rural area, all in the genus Sarcophaga, was shown to contain the virus. This specimen produced symptoms of poliomyelitis in a Philippine monkey but was negative in a rhesus monkey. Two other specimens of flies caused questionable symptoms in the first animal inoculated, but the agent could not be passed to a second monkey. The results have been thought to be open to criticism in that rhesus monkeys were used for most tests, and the statement has been made that they are insusceptible to fly virus.

In the past a wide variety of flies has been incriminated in the pools which have yielded virus; the actual species involved have usually not been ascertained. Nevertheless, Musca domestica, the common house fly, has not been prominent in the collections, while the blow fly (Calliphora vomitoria) and several other species have been.

The usual assumption has been that flies acquire their contamination from human excreta, but no direct evidence that they do has been presented. A certain significance might be applicable if the species of flies

which habitually feed on human stools were known. Accordingly, fresh normal adult human stools were placed as bait in cone-shaped fly traps in numerous areas throughout Michigan during a period when poliomyelitis was not prevalent. The field identifications of the collections made are given in table 2.

Table 2.—*Species of Flies That Were Trapped with Human Stools as Bait*

	Number Trapped
Phaenicia sericata and a small number of Lucilia spp....	2,048
Phormia regina and Protophormia terrae-novae.........	629
Sarcophaga spp.	616

Cynomyopsis cadaverina	29
Musca domestica	17
Stomoxys calcitrans	7
Callitroga macellaria	6
Fannia canicularis	1
Miscellaneous identified and unidentified specimens........	856

The same results were obtained from trappings of flies in rural Tennessee during an epidemic where ample opportunity to feed on feces was provided. It was obvious that the "blow," "flesh" and "green bottle" flies, and not the house fly, were abundantly attracted to human excreta as used in our methods of collection. One should not be misled, however, into believing that the house fly is not attracted to human excrement under some circumstances. These data show that the species encountered were those which had been present in previous collections described as containing the virus, and they support the idea that the human stool is a likely source of the virus.

In order to complete the chain of evidence and prove that flies are capable of acquiring the virus from human excreta, collections were made in Ann Arbor in traps baited with fresh stool from a patient with acute poliomyelitis. The stool was proved to contain the virus by inoculation of a monkey, and flies trapped at the same time but not allowed to feed on the stool were shown to be free of the virus. After separating into species the flies which had fed on the virus-containing stool, seven pools were inoculated intracerebrally in both rhesus and Philippine monkeys and one pool in rhesus monkeys only. One specimen consisting of 183 Phaenicia sericata produced symptoms in both types of monkeys. Another pool of 7 Phormia regina and 1 Callitroga macellaria produced symptoms in a Philippine monkey but none in the rhesus. Two other pools, one containing 13 small feces-inhabiting flies of several species, including Gymnodia arcuata and Myiospila meditabunda, 1 Fannia canicularis, 3 Muscina assimilis and 3 Musca domestica, and the other containing 11 undetermined muscids, 14 Muscina assimilis and Muscina stabulans, 6 Callitroga macellaria and 2 Musca domestica, produced symptoms in rhesus but not in Philippine monkeys. It is interesting that not just one but several species of flies were capable of acquiring the virus, while the house fly was essentially uninvolved. It is also of interest that three pools of flies produced symptoms in rhesus monkeys and that two of these pools did not produce disease in Philippine monkeys. Other workers have clearly expressed the opinion that rhesus monkeys are not susceptible to infection with virus from naturally caught flies.

The evidence clearly demonstrates that the stool of a patient with poliomyelitis can serve as a source of virus for certain flies, which thus become potential vectors of the infectious agent.

Virus was not isolated from normal liver and fruit bait on which the disease-conveying flies subsequently fed, but it is felt that this step in the transmission still offers possibilities which further experimentation should clarify.

It should be added that the virus isolated from flies in this manner has been repeatedly passed in monkeys and has been identified by means of monkey neutralization tests as serologically similar to the Rockford, Ill. (1945) and Minneapolis (1946) strains. It also has a high intracutaneous pathogenicity in monkeys.

SEROLOGIC STUDIES

From time to time the serums of animals associated with the households of patients and having a history of recent illness have been tested for neutralizing antibodies to the mouse-adapted Lansing strain of poliomyelitis virus. Two cows, a rabbit, a horse and several chickens have been found entirely lacking in antibodies.

Forty-six wild rats from epidemic areas of Buffalo and Detroit whose tissues were examined for virus were first bled and their serums tested for Lansing strain neutralizing antibodies.[12] The serums of 45 of these rats showed no evidence of antibodies, but the serum of the remaining rat repeatedly neutralized the Lansing strain of virus. Two other rats were found to maintain circulating antibodies to a strain of Theiler's spontaneous mouse encephalomyelitis virus.

SUMMARY

Attempts to isolate the virus of poliomyelitis from various extrahuman sources in epidemic areas have been made by inoculation of monkeys and of cotton rats and mice.

Thirty-three wild mice, 112 wild rats, 3 muskrats, 4 cats, 1 horse, many chickens, cows and hogs, and 43 pools of insects, 38 of which were flies, representing approximately 15,300 individual specimens, have been so tested.

In addition 24 samples of sewage, 2 of sludge, 1 of soil, 10 of water and 3 of milk have been examined.

The animals, the insects and the other specimens were collected during epidemics of the disease and usually from locations in close proximity of patients.

A mouse-paralyzing agent was isolated from one pool of tissues from wild rats caught in Fort Worth, Texas, in 1943. It has not been identified.

Of 38 pools of flies, one collection of 23 Sarcophaga spp. from rural Tennessee, 1945, was shown to contain poliomyelitis virus.

In all other attempts to isolate the virus the results were negative.

The serums of 2 cows, a horse, a rabbit and 46 wild rats have been tested for neutralizing antibodies to the Lansing strain of virus. All were negative with the exception of that of a wild rat obtained from Detroit in 1944, which had definite virus-neutralizing capacity.

Fly trappings, using fresh normal adult human stool as bait, have shown that certain flies, Phaenicia, Phormia, Sarcophaga, Muscina and Calliphora, are the predominant genera attracted to human feces with the methods of collection used; the common house fly, Musca domestica, is not.

Virus from feces of a patient with poliomyelitis was actually taken up by flies and recovered by inoculation of rhesus monkeys.

ABSTRACT OF DISCUSSION

Dr. R. R. Spencer, Washington, D. C.: This meeting is a high point in the progress of knowledge of viruses. I shall limit my discussion to the possibility that viruses are related to cancer, presented by Dr. Kidd. The virus field and the cancer field are converging. It is difficult to believe that all types of cancer are due to a single invasive parasitic virus, and discussion is meaningless until more is learned about cells, which are the units of life, and by cells I mean virus particles, as well as body cells. Viruses are rather complex. Certainly, no one has yet grown the mammillary cancer virus; if there be a virus, in tissue culture or in chick embryo, although many of the parasitic viruses have been. Probably it comes down to a question of definition. If you mean by virus, external invasive parasitic organisms, I doubt that mammillary cancers are due to that kind of agent. If, on the other hand, you mean filterable intracellular components, perhaps detached genes or plasmagenes, then each type of cancer may have its own specific kind of intracellular component. There is no clearcut dichotomy anywhere in biology. In other words, there is a gradual change in structure and function all the way from the simplest forms of living things to the most complex, and one should not attempt to make clearcut definitions too quickly. One final point, cancer transplants elicit a rich blood supply and a supporting stroma, as every pathologist knows. They do not, however, elicit a nerve supply. The hyperplasia that results from infection seems to be definitely a defensive mechanism. I do not believe the hyperplasia of cancer is defensive. The body, certainly in the early stages of cancer, does not seem to recognize its presence. I like therefore to think of cancer as an "autoparasite." Regardless of all theories that Dr. Kidd mentioned as to the causation of cancer, and regardless of all the various inciting agents that are known, the end result is always the same. It is one of our own cells that has turned parasite.

Dr. James P. Leake, Washington, D. C.: With reference to Dr. Smadel's paper, I shall make a nonpathologic comment, that for one very important disease, smallpox, the key diagnosis is not in the laboratory but clinical. It must be prompt. Any case of purpura with fever should be considered smallpox as far as precautions are concerned, such as vaccination of those that are in the entourage, until another diagnosis is clear. In the second place, the dependent diagnosis should be made principally not on history, not on the character of the lesions, but on the distribution of the lesions. All of us can be mistaken at times, but it is safer to take precautions.

Dr. E. W. Schultz, Stanford University, Calif.: Little reference has been made to the limitations of specific therapy of virus diseases. It is important to remember in this connection that antibodies are much too large to enter cells and that there is little reason to expect therapeutic effects with immune serums after the invasion of susceptible cells has occurred. The same applies in general to chemotherapy. It would appear that future attempts to control these diseases will have to center largely around possible means of modifying the native susceptibility of vulnerable cells or preventing their initial invasion by the timely use of prophylactic agents. Virus diseases, more than any other group of diseases, depend on prophylactic measures for their control. Once infection has occurred the disease is largely out of control.

Dr. J. E. Smadel, Washington, D. C.: Viruses differ from one another. Nevertheless, all viruses have certain biologic properties in common, since they are obligate intracellular parasitic microbes. There is a tendency to think that the similarities in basic biologic properties extend to close similarities in physical, chemical and immunologic properties. The fallacy of this generalization has been touched on but not emphasized. The electron micrographs of Dr. Wyckoff do not bring out these differences in viruses as well as do other methods. Thus, certain of the plant viruses have a relatively simple chemical structure, being composed solely of nucleoprotein, which behaves as a single antigenic substance. On the other hand, the large virus of vaccinia contains protein, nucleoprotein, carbohydrate, lipid and minerals; in fact, it has the biochemical characteristics of bacteria or protoplasm. The complexity of this virus is further indicated by the fact that it contains at least five different antigenic structures. These viruses represent the two ends of the spectrum, agents in between show varying grades of similarity to the end viruses. I wish to reiterate the heresy which I mentioned earlier—don't ask for isolations. The Army has had greater experience in attempts at isolation of viruses than any other group in the United States. We consider it relatively unprofitable for the routine diagnosis of virus and rickettsial disease.

TRANSURETHRAL RESECTION FOR VESICAL DYSFUNCTION IN CASES OF TABES DORSALIS

JOHN L. EMMETT, M.D.
and
JOHN B. BEARE, M.D.
Rochester, Minn.

In 1941, we reported the results of a study of vesical dysfunction in cases of tabes dorsalis and analyzed the results of transurethral resection in 35 of the cases.[1] In these cases, the results of transurethral resection were very good. We recently have made a follow-up study of these 35 cases and of 44 additional cases of tabes dorsalis in which transurethral resection has been performed since Dec. 31, 1940. These two groups of cases form the basis of the present report.

In making such a study, it must be emphasized that it is impossible in every case to distinguish accurately vesical dysfunction caused by the tabetic state alone from that which results from hypertrophy of the prostate gland or other obstruction of the vesical neck in a case in which tabes dorsalis is only a coincidental finding and of no urologic importance. It is true that the extremes of these conditions are rather easily recognized, but intermediate conditions may be difficult to classify. The chief reason for this difficulty lies in the basic neuromechanics and obstructive factors involved in the disability. The neurophysiology of normal micturition has been described elsewhere,[2] and it is so well known that description here seems unnecessary. The tabetic process damages the posterior spinal ganglions, the posterior sensory roots and the posterior sensory columns of the spinal cord. This may block not only the impulses which pass through the sensory component of the simple spinal reflex arc and which control micturition (the level of which is in the sacral portion of the cord) but also may block the impulses which pass through the sensory part of the suprasegmental conditioning reflex and mediate vesical control by means of subconscious or conscious inhibitory impulses from the higher levels. With involvement of the sensory component of the lower reflex arc, it is apparent that more and stronger impulses would be necessary to incite reflex vesical contraction. This would result in progressive vesical distention, loss of tone and atony. Damage to the sensory component of the suprasegmental conditioning reflex would interfere with the stimuli which incite the proper flow of inhibitory impulses down the corticospinal tracts to supply subconscious and voluntary control of the lower reflex arc for micturition. In other words, the patient might not experience the desire to micturate until greater and greater distention of the bladder occurs, and the micturition could begin without the patient's being aware of it.

It is easy to visualize how such a lesion can give rise to urinary retention and incontinence. The bladder

[2] Emmett, J. L., and Dunn, J. H.: Transurethral Resection in the Surgical Management of Cord Bladder, Surg., Gynec. & Obst. **83**: 597-612 (Nov.) 1946.

becomes increasingly stretched, loses its tone and becomes atonic. There results an imbalance between the detrusor urinae muscle and the vesical neck,[3] which results in residual urine and retention. Under such circumstances, even a normal- appearing vesical neck may be obstructive. Any obstruction of the vesical neck, even of a minimal degree, may increase the imbalance, and the fact that most patients who have tabes dorsalis are more than 40 years of age stipulates that almost all men who have this disease have some degree of prostatic hyperplasia, although it may be of mild degree.

Our experience with this problem has left us with the impression that most of the urinary incontinence in tabetic patients may be explained in two ways: (1) overflow from a distended bladder and (2) involuntary micturition caused by reflex emptying of the bladder not properly controlled by the suprasegmental conditioning reflex, the sensory components of which have been damaged. To put it simply, since the patient is not aware that micturition is about to occur, sufficient inhibitory impulses are not sent down from the conscious or subconscious level to prevent it.

It is apparent, therefore, that the over-all problem of vesical dysfunction in tabetic patients is composed of three rather ill defined parts; namely, (1) vesical dysfunction arising primarily from the neurogenic lesion caused by the tabetic state, (2) obstruction of the vesical neck in a case in which tabes dorsalis is only a coincidental finding and plays no part in the vesical dysfunction and (3) a combination of both factors. It is our feeling that most instances of vesical dysfunction belong in the last group.

In our previous article[1] on this subject, we analyzed the results in 35 cases of tabes dorsalis in which transurethral resection had been performed. It was apparent from this study that both residual urine and urinary incontinence could be eliminated in almost all cases. It was thoroughly demonstrated that prostatic operation could be done with no more concern or fear of postoperative incontinence in the tabetic patient than in the nontabetic patient. It also was observed in this series of cases that the amount of tissue removed was not great; it was less than 5 Gm. in many cases. This observation further emphasized that minimal amounts of obstruction at the vesical neck can produce vesical decompensation in the weakened tabetic bladder.

Inasmuch as minimal degrees of obstruction of the vesical neck or even a normal- appearing vesical neck can be the precipitating factor in vesical dysfunction in cases of tabes dorsalis, one might logically reason that minimal degrees of postoperative scarring or contraction of the vesical neck occurring after transurethral resection could cause sufficient obstruction to produce a recurrence of the vesical dysfunction and residual urine. In such an event, it could also be assumed that transurethral removal of the postoperative scar tissue or removal of a recurring adenoma might again yield a good result. In short, we have wondered whether any of the 35 patients who were operated on prior to Jan. 1, 1941, have had to undergo further treatment because of a recurrence of their former symptoms. To investigate this problem we have reviewed all of these cases. In all of these cases, more than six years have elapsed since transurethral resection first was performed at the Mayo Clinic. One of the patients has returned to the clinic for further treatment. Letters of inquiry were sent to all of the other patients, and thirty-one replies were received. Follow-up data, therefore, are available in 32 of the 35 cases. In 16 of the 32 cases, the patients were alive at the time of inquiry. In 9 of these 16 cases, the letters indicated that the patients did not have any symptoms referable to the urinary bladder; there was no urinary frequency or incontinence. In 6 other cases, the patients reported that their vesical function was satisfactory except for the presence of varying degrees of urinary frequency and some nocturia. All of the 15 patients felt that they were emptying their bladders completely, although some stated that the urinary stream was not so large as it had been immediately after the transurethral resection. (This would indicate that these patients have had a slight degree of postoperative contracture or scarring of the vesical neck.) In the letters of inquiry, we requested the patients to have a determination of the amount of residual urine made, if possible. All of the 6 patients who complied with this request reported that they were emptying their bladders completely.

The case in which the patient returned to the clinic because of a recurrence of his former symptoms is of sufficient interest to be presented here in abstract form, as it is illustrative of the general problem.

A man aged 42 years first came to the clinic in December 1918. His chief complaint was difficulty with his urinary bladder, which consisted of nocturnal incontinence, a diurnal urgency type of incontinence and difficulty in initiating and maintaining the urinary stream. In addition, he complained of loss of sexual power, an unsteady gait (especially at night) and weakness of his legs. He stated that he had had a penile chancre at the age of 21 years.

Examination disclosed tabes dorsalis. The Wassermann reaction on the serum and cerebrospinal fluid was positive. Romberg's sign was present. Urologic examination disclosed the presence of 400 cc. of infected residual urine. Cystoscopy revealed a large atonic bladder with little if any trabeculation. The diagnosis was tabetic cord bladder. The patient was advised to employ periodic vesical lavage.

The patient returned to the clinic twenty-one years later; that is, in June 1939. His chief reason for seeking medical aid at this time was urinary incontinence and foul-smelling urine that made it impossible for him to live in normal society. He also complained of "lightning" pains around the abdomen. Vesical lavage had produced some relief of the urinary symptoms for several years, but in the past two or three years the incontinence had become so great that he had been forced to wear a rubber urinal.

Neurologic examination revealed the same signs of tabes dorsalis that had been noted at his examination twenty-one years previously. The bladder contained 1,000 cc. of foul, infected, residual urine. Cystoscopy disclosed a large atonic bladder with minimal trabeculation. The prostatic urethra and vesical neck appeared to be relaxed, dilated and "pulled open" as a result of the vesical distention. There was adenomatous enlargement, grade 1, of all three lobes of the prostate gland. The diagnosis was tabetic cord bladder associated with minimal prostatic hyperplasia.

A transurethral resection was performed on June 30, 1939, with the Thompson cold punch resectoscope. The removal of 8 Gm. of tissue seemed to open the prostatic urethra widely. Pathologic examination of the excised tissue revealed adenofibromatous hyperplasia. The patient was able to empty his bladder completely, although it was necessary for him to use considerable abdominal straining. Several minutes were required to empty the bladder completely. The urinary incontinence was relieved entirely. Owing to the sensory involvement, he never regained the desire to micturate; he therefore was instructed to micturate every three hours. The urinary infection was eliminated and the patient was dismissed from our care.

---

[3] Emmett, J. L.: Urinary Retention from Imbalance of Detrusor and Vesical Neck: Treatment by Transurethral Resection, J. Urol. 43: 692-704 (May) 1940.

His next visit to the clinic was seven years later; that is, in June 1946, when he was 70 years of age. He stated that his urinary function had been satisfactory for about five years after the last transurethral resection. In the two years before he returned to the clinic, previous symptoms had returned gradually. He again complained of urinary incontinence and infected urine. Urologic examination revealed that his bladder contained 600 cc. of residual urine. Cystoscopy revealed a moderate degree of postoperative contracture of the vesical neck and some residual or recurrent adenomatous hyperplasia in both lateral lobes of the prostate gland, near the apex of the gland. The bladder was large and atonic.

Transurethral resection was performed on June 11, 1946. As the resection proceeded, it became apparent that there was a substantial amount of adenomatous tissue at the apex of the prostate gland. Twelve grams of tissue was removed. Examination of the excised tissue disclosed adenofibromatous hyperplasia. The result was excellent; the patient was able to empty the bladder completely with a good stream. It was still necessary for him to use abdominal straining and he was advised, as he had been after the previous operation, to empty his bladder regularly every three or four hours.

ANALYSIS OF FORTY-FOUR CASES OF TABES DORSALIS IN WHICH TRANSURETHRAL RESECTION WAS PERFORMED

We have been interested to know whether our results with transurethral resection in tabetic patients will continue to be as favorable as indicated in our previous report. Accordingly, we have made a study of 44 cases of tabes dorsalis in which transurethral resection was performed at the clinic in the years 1941 to 1945, inclusive. As mentioned in our original article, we feel that it is impossible to determine with any degree of accuracy in every case the proportion of the vesical dysfunction caused by the primary neurogenic atony and that produced by obstruction of the vesical neck. In most cases there was no question but that the tabetic condition was the predominating factor; in other cases, it seemed definite that the predominating factor was obstruction at the vesical neck. It is entirely possible that in a few cases the tabes dorsalis was only a coincidental finding and did not contribute to the vesical dysfunction. In the absence of an accurate method of distinguishing these conditions, it seems best to consider them as a single group.

Age and Sex.—Of the 44 patients, 43 were men and 1 was a woman. All except 4 were 50 or more years of age (table 1), which substantiates the thesis that most of the patients are in the age of prostatism when the vesical symptoms become sufficiently disturbing to require medical care.

TABLE 1.—*Age of Patients in Forty-Four Cases of Tabes Dorsalis in Which Transurethral Resection Was Performed*

Age, Years	Cases
40 to 49	4
50 to 59	18
60 to 69	16
70 to 79	6

Urinary Incontinence and Residual Urine.—Seventeen of the 44 patients complained of some type of "incontinence." In 6 cases, the incontinence was nocturnal only and in 1 case it was of a precipitate urgency type. In the remaining 10 cases, the urinary leakage occurred during both the day and night and varied in degree from a mild type consisting of an occasional involuntary spurt of urine to a more or less continual overflow type of dribbling from a distended bladder. In all except 1 case, the bladder contained more than 200 cc. of residual urine; in 12 of the cases, more than 300 cc. of residual urine was present. The largest amount found in any of these 17 cases was 1,200 cc. The amount of residual urine present in the entire group of 44 cases is shown in table 2.

TABLE 2.—*Amount of Residual Urine Before Transurethral Resection in Forty-Four Cases of Tabes Dorsalis*

Residual Urine, Cc.	Cases Number	Percentage
More than 500	8	18
100 to 500	22	50
Less than 100	14	32

Type of Obstruction of the Vesical Neck.—Consistent with our previous experience, the degree of obstruction at the vesical neck was not great. Contractures of the vesical neck, small adenomatous collars and a small degree of hypertrophy of the lateral and median lobes predominated. It should be pointed out that in many of the cases cystoscopy suggested that the vesical neck was relaxed and dilated and was probably not causing any obstruction. This appearance is due to the distended bladder, which has pulled open and stretched the vesical neck. (The surgeon should not let this condition deter him from performing a transurethral resection, as the results of transurethral resection in this type of case are as good as in any other.) In the majority of cases, it was necessary to remove less than 10 Gm. of tissue (table 3), while in only 9 cases was it necessary to remove more than 20 Gm. of tissue. In some cases, it was difficult to demonstrate obstruction at the vesical neck until resection actually was begun.

TABLE 3.—*Weight and Type of Tissue Removed by Transurethral Resection in Forty-Four Cases of Tabes Dorsalis*

Weight of Tissue, Gm.	Cases	Type of Tissue Adenofibromatous Hyperplasia	Carcinoma	Inflamed Smooth Muscle
0 to 3	2	1	..	1
4 to 5	5	4	..	1
6 to 10	18	17	..	1
11 to 20	10	10	..	..
21 to 50	9	7	2	..
Total	44	39	2	3

Results.—The results of transurethral resection were most satisfactory and essentially paralleled those obtained in our previous series. The results were classed as good in 39 cases and as fair in 3 cases. Two patients were unimproved. By the term "good," we mean that the patient is able to void with a good stream, can empty the bladder completely and has no urinary incontinence.

Of the 17 patients who complained of urinary incontinence prior to operation, 15 secured excellent results and complete relief of the incontinence. One patient, although able to empty his bladder completely, continued to have a moderate degree of urinary urgency while the remaining patient still complains of nocturnal enuresis and of difficulty in expelling his urine.

Reviewing the 5 cases in which the results were not entirely satisfactory, one gains the impression that further cystoscopy is indicated and that in some of the cases removal of additional tissue would improve the vesical function. In such cases, it often requires careful observation and judgment to recognize and remove minimal amounts of tissue from the vesical neck. Removal of such tissue may make the difference between an excellent and an unsatisfactory result.

TRANSURETHRAL RESECTION IN TABETIC WOMEN

In our previous study, it was pointed out that in cases of tabes dorsalis vesical dysfunction is much more common among men than women. This is no doubt explained by the fact that obstruction of the vesical neck is so much more common in men than it is in women. Nevertheless, vesical dysfunction with residual urine and urinary incontinence does occur in women. This condition can also be cared for by transurethral resection. The following case is illustrative of the condition.

A woman aged 62 years came to the clinic on Oct. 22, 1945. She complained of a girdle type of pain which encircled the left side of the thorax at the level of the angle of the scapula. The pain had been present intermittently for several years. It recently had become so severe that morphine had been necessary for relief. She also complained of having "lost control of her bladder." This had consisted chiefly of nocturnal incontinence; however, it recently had begun to be troublesome during the day. The amount of urine that was expelled in this manner was sufficient to wet her clothes.

Her past history suggested that she probably had had a chancre at the age of 19 years and that the lesion never had been treated. For many years, she had "prided herself" on the length of time she could go without voiding. More recently, she had experienced moderate difficulty in initiating the urinary stream; recently, incontinence had developed and had become annoying.

Neurologic examination revealed typical signs of tabes dorsalis. The Wassermann reaction and results of flocculation tests on the blood and cerebrospinal fluid were strongly positive, and examination of the spinal fluid revealed a paretic colloidal gold curve. The girdle pain was interpreted as being due to a typical tabetic crisis.

Urologic examination revealed 350 cc. of residual urine. Cystoscopy revealed a large atonic bladder and trabeculation, grade 1. The urethra was very short. The vesical neck did not appear to be causing a great deal of obstruction. An excretory urogram did not disclose any abnormality of the kidneys. The diagnosis was tabetic cord bladder.

Transurethral resection was performed on Nov. 26, 1945, by means of the small punch resectoscope. Fifteen pieces of tissue were removed from the entire circumference of the vesical neck. The results of the operation were excellent. When the catheter was removed, the patient was able to void well with a good stream and could empty her bladder completely. The diurnal and nocturnal incontinence were completely eliminated. On her dismissal, the patient was instructed to micturate regularly at least every three hours.

COMMENT

It is our opinion that vesical dysfunction associated with tabes dorsalis is no longer a therapeutic problem of any importance, since consistently good results may be obtained by means of transurethral resection of the vesical neck. The explanation of how transurethral resection corrects vesical dysfunction in this disease seems relatively simple, although it must be admitted that some points are more or less theoretic. The elimination of residual urine is brought about by weakening the vesical neck sufficiently to permit the weakened atonic bladder, aided by intra-abdominal and, if necessary, manual compression, to expel the urine completely. The elimination of the residual urine also relieves the incontinence in cases in which the patients are suffering from an overflow type of incontinence. The explanation of the relief of incontinence that is principally an involuntary type of micturition also seems fairly simple. The elimination of residual urine increases the reservoir capacity of the bladder. The patient is instructed to micturate regularly every three or four hours to prevent undue distention of the bladder so that the chance of involuntary micturition is minimized. He is instructed to take the time and make the effort to empty his bladder completely at each micturition. In some cases in which advanced sensory damage is present, the patients never may regain the desire to micturate. Such patients must be carefully taught to micturate at regular intervals and not to wait for the desire to micturate. Inasmuch as the bladder is emptied completely at each voiding, the urine may be kept free of infection; therefore, for all practical purposes, the vesical function may be considered normal.

One word of caution should be given. Inasmuch as small degrees of obstruction of the vesical neck can precipitate vesical dysfunction in cases of tabes dorsalis, small degrees of postoperative contracture may conceivably cause a recurrence of the obstruction. Because of this, such patients should be reexamined at yearly intervals to determine whether any residual urine is present. If it is, cystoscopic reexamination of the vesical neck should be performed and any scar tissue should be excised.

POLYMYXIN

A Note on Experimental and Clinical Investigations

EMANUEL B. SCHOENBACH, M. D., MORTON S. BRYER, M. D.,

ELEANOR A. BLISS, Sc. D., and PERRIN H. LONG, M. D.

Baltimore

In May 1947, Benedict and Langlykke[1] reported that sterile culture filtrates of Bacillus polymyxa in dilutions of 1:1,000 inhibited the growth of Brucella bronchiseptica in culture. Shortly after this report, Stansly, Shepherd and White[2] independently described the isolation of an antibiotic substance from B. polymyxa which they named "polymyxin." This antibiotic was shown by them to be effective only against gram-negative organisms in vitro, and to possess a high degree of therapeutic activity against experimental infections produced in mice by the inoculation of Klebsiella pneumoniae or Pasteurella multocida. It was also effective against experimental fowl typhoid infections in chicks. Subsequently, Stansly and Schlosser[3] established the identity of polymyxin as a new antibiotic and developed a method for its bio-assay. Not long after the two original reports on this antibiotic appeared, Ainsworth, Brown and Brownlee[4] announced that they had isolated an antibiotic, active against gram-negative organisms, from cultures of Bacillus aerosporus Greer. To this agent they gave the name

"aerosporin." Recently, Brownlee and Bushby [5] have described in detail the bactericidal, toxicologic and pharmacologic properties, and experimental therapeutic effectiveness of aerosporin, while Swift [6] has reported that this antibotic is of some value in the treatment of whooping cough in children. Although polymyxin and aerosporin are derived from similar micro-organisms, recent comparisons of the two products suggest that they are dissimilar in chemical composition. [7]

We wish to report briefly upon the experimental and clinical observations which we have made during the past six months with polymyxin (hydrochloride). This antibiotic in vitro is most effective in an acid medium, is relatively heat stable and loses little of its activity in the presence of serum. The strains of Escherichia coli, Aerobacter aerogenes and K. pneumoniae which have been tested are susceptible to 0.3 microgram of polymyxin per cubic centimeter when an inoculum of 200,000 bacilli is used. Pseudomonas aeruginosa is slightly more resistant to this antibiotic, while the strains of P. vulgaris and N. intracellularis so far tested in vitro appear to be completely resistant. Polymyxin in its effective concentrations appears to be bactericidal in its action on susceptible micro-organisms. Like Stansly et al. [2], we have found it was impossible to produce resistant strains from susceptible organisms in vitro.

The acute toxicity of polymyxin was determined in mice by single subcutaneous injections and the LD 50 was found to be 50 to 300 mg. per kilogram. While dogs survived single intravaneous injections of 10 to 15 mg. per kilogram of body weight, single intravenous injections of 25 mg. per kilogram produced death. Dogs tolerated 5 and 10 mg. of the antibiotic per kilogram when given injections twice daily by the intramuscular route for seven days. Intrathecal injections of 1 and 5 mg. of the drug in dogs produced no untoward reactions, while 10 mg. produced transient paresis of the hind legs.

Ninety minutes after dogs had received single intramuscular doses of 5 and 10 mg. per kilogram, serum concentrations of 2.5 and 5.0 micrograms of polymyxin per cubic centimeter were recorded. Three and one-half hours after these doses, serum concentrations of 2.5 and 1.25 micrograms per cubic centimeter were noted. When dogs were given 5 and 10 mg. of the compound per kilogram twice daily for seven days, serum concentrations of 10 to 20 micrograms of polymyxin per cubic centimeter were observed. The antibiotic was not detected in the spinal fluid of dogs in which high serum concentrations of polymyxin were present. When polymyxin was administered to human beings in divided doses by the intramuscular route at intervals of three hours in amounts not to exceed a total daily dose of 3 mg. per kilogram of body weight, concentrations of 0.6 to 1.3 micrograms per cubic centimeter were noted in the serum after twenty-four hours of therapy. Detectable amounts of polymyxin began to appear in the urine twelve hours after the initiation of the dosage schedule just described. After twenty-four hours of its administration, effective bactericidal concentrations of the antibiotic were found in the urine. In 1 person, suffering from purulent meningitis and treated with polymyxin, none of the agent was detected in the spinal fluid.

As is shown in the table, single doses of 1 mg. of polymyxin per kilogram of body weight administered by the subcutaneous route protected the majority of mice which had been previously infected by the inoculation of 1,000 minimum lethal doses of either K. pneumoniae (type A) or Hemophelus influenzae (type B) by the intraperitoneal route. These results confirmed previous observations on the therapeutic effectiveness of this antibiotic in experimental gram-negative infections. [2] Comparable experimental infections treated with streptomycin in doses of 1 or 5 mg. per kilogram of body weight were used as therapeutic controls. Under the conditions of the test, polymyxin appeared to be five to ten times more effective in the control of these experimental infections than was streptomycin. Furthermore, it has been noted that while neither a bacteriostatic nor bactericidal effect could be demonstrated against Neisseria intracellularis in vitro, polymyxin had a definite curative effect in experimental meningococcic infections in mice. This paradox is being investigated.

Table 1.—*Comparison Of Streptomycin and Polymyxin*

Drug	Dose, Single (Subcutaneously) Mg./Kg.	Inoculum*	Deaths on Day Indicated						Survivals After Six Days	
			1	2	3	4	5	6	Number	Percentage Total
Control	—	K. pneumoniae† Type A	10	–	–	–	–	–	0	0.0
Streptomycin	1 5	K. pneumoniae Type A†	1 –	4 –	9 3	1 –	– –	– –	5 7	25.0 70.0
Polymyxin	1 5	K. pneumoniae Type A†	– –	– – –	1 –	2 –	– –	– –	17 20	85.0 100.0
Control	—	H. influenzae Type B‡	9	–	–	–	–	–	1	10.0
Streptomycin	1 5	H. influenzae Type B‡	16 2	– –	– –	– –	– –	– 1	4 7	20.0 70.0
Polymyxin	1 5	H. influenzae Type B‡	– –	1 –	– –	– –	– –	– –	19 20	95.0 100.0

*In all instances 1,000 lethal doses were given.

†K. pneumoniae, type A, was injected intraperitoneally.

‡H. influenzae, type B, was injected intraperitoneally in 5 per cent hog gastric mucin.

Polymyxin in total daily dosages of up to 5 mg. per kilogram of body weight, given in a special buffer solution (pH 7.4) at intervals of three hours has been used to treat patients seriously ill with infections due to Pseudomonas aeruginosa, K. pneumoniae, Hemophilus pertussis, and Brucella abortus. To date, the results have been such as to demonstrate clearly that polymyxin has a therapeutic effect against infections produced by these organisms in human beings. Too few patients have been treated to make any definite statements in regard to the clinical toxicity of polymyxin. One instance of fever, possibly due to the drug, has been noted. Other toxic reactions undoubtedly will occur.

CONCLUSION

Polymyxin is a new antibiotic uniquely and highly active in vitro against certain varieties of gram-negative micro-organisms. Its acute toxicity in experimental animals is considerably greater than that of penicillin or streptomycin. After intramuscular injection of the antibiotic, it promptly enters the blood stream, but it does not pass the blood-brain barrier. It is excreted slowly in the urine.

In certain experimental infections produced by the inoculation of gram-negative organisms in mice, polymyxin appears to be definitely more effective than streptomycin. The results following its use in certain types of clinical infections produced by gram-negative bacilli are interesting. However, careful clinical trials of this compound in selected and suitable types of infections must be made before the therapeutic effects of polymyxin can be evaluated.

Clinical Notes, Suggestions and New Instruments

DEVELOPMENT OF APLASTIC ANEMIA DURING THE USE OF STREPTOMYCIN

Report of Two Cases

CAPTAIN V. F. DEYKE, and
LIEUTENANT COLONEL J. B. WALLACE,
Medical Corps, United States Army

Case 1.—A white man aged 46 with moderately advanced pulmonary tuberculosis was admitted to Fitzsimons General Hospital in January 1947. On April 1 the patient was started on 2 Gm. of streptomycin daily, intramuscularly in five equally divided doses. There was no history of blood disorder or any evidence of such on periodic examinations until June 19, at which time the erythrocyte count was 3,100,000, the leukocyte count was 3,500, neutrophils 54 per cent and lymphocytes 46 per cent. Streptomycin was discontinued on that date. On June 29 the leukocyte count was 2,000 with 91 per cent lymphocytes. The platelets were markedly decreased. On that date, the usual vigorous measures were begun to combat aplastic anemia. In spite of this the blood picture continued to deteriorate until July 7, when the erythrocyte count was 2,800,000. The leukocytes measured 800, of which 2 per cent were neutrophils and 98 per cent lymphocytes. No platelets were seen. The patient died July 8, nineteen days later. Autopsy revealed pronounced hypoplasia of bone marrow. The proximal end of the femur was filled with a soft yellow fatty material. A similar change was noted in the rib bone marrow. Microscopically the marrow was predominantly replaced by fat, with scattered occasional islands of hemopoietic tissue.

Case 2.—A white man aged 27 with active moderately advanced tuberculosis was admitted to the hospital Feb. 5, 1947 with a history suggesting onset of illness two months previously. On March 17 he was started on 2 Gm. of streptomycin daily administered intramuscularly in five equally divided doses. Periodic blood counts revealed no abnormality until June 20, when a depression of all blood elements was noted. Streptomycin therapy was discontinued immediately, and the usual vigorous efforts were made to combat aplastic anemia. The blood picture has deteriorated to this writing (July 17) when the red blood cell count is 1,400,000, the white blood cell count 1,100, neutrophils 1 per cent and lymphocytes 99 per cent; no platelets are seen. Repeated sternal marrow examinations reveal a decided diminution in the number of the young red and granulocytic series. Recovery is doubtful.

COMMENT

Some 400 patients have been, or are being, treated with streptomycin to date at this hospital. In 2 patients from this number a serious depression of blood elements developed during streptomycin therapy, beginning on the seventy-ninth and ninety-fifth days of treatment. Neither patient appeared to have disseminated hematogenous tuberculosis. One patient had received an occasional "seconal sodium" tablet and the other patient had received some diphenhydramine hydrochloride. It is our opinion that neither of these drugs was the causative agent.

Review of the literature indicates that of some 900 patients, other than the series at the Fitzsimons General Hospital, treated with streptomycin, 8 have shown a relatively mild leukopenia, 6 of whom had a relative neutropenia. These were self limiting. There is reported 1 case of agranulocytosis, but no mention is made as to its severity and outcome.[1]

Council on Physical Medicine

The following article has been adopted by the Council on Physical Medicine.

The Council wishes to express its appreciation for the valuable cooperation of the Consultants on Ophthalmic Devices in reviewing and adopting this article. The consultants are Drs. Walter B. Lancaster, chairman; Thomas D. Allen, S. Judd Beach, Conrad Berens, Frederick C. Cordes, Alfred Cowan, William H. Luedde, Lawrence T. Post, Avery D. Prangen and Kenneth C. Swan.

HOWARD A. CARTER, Secretary.

TINTED LENSES

ALFRED COWAN, M.D.
Philadelphia

The following statement is made for the benefit of the public and for those ophthalmologists who are insufficiently informed and therefore misled by the extravagant and often untrue claims of a number of manufacturers of trademarked tinted lenses.

The vogue for tinted lenses has reached such an extent that most laymen and many ophthalmologists believe that the eyes need protection not only against daylight but against any light, even night light. Informed ophthalmologists disapprove the widespread, continuous and indiscriminate use of tinted lenses and object to the methods and wording of the advertisers of these glasses.

The purpose of light-filtering glasses is to protect the eyes against painful or harmful light. Unless the eyes are sick or abnormally sensitive, dark glasses are indicated only in the presence of extraordinary, excessive or misdirected light. Healthy, properly corrected eyes should be well able to tolerate bright sunlight unless it is reflected directly into the eyes by water, snow, sand or the like. The sole purpose of so-called "sun glasses" is to reduce considerably the amount of direct or reflected sunlight on those occasions when the amount is so great that it interferes with vision. On the occasions when protection is necessary the glasses should be dark enough to absorb from 60 to 75 per cent of the light and they should be colorless—smoke or gray.

Any person with normally healthy eyes should be comfortable under ordinary bright sunlight. Those who would be annoyed by less than unusually brilliant sunlight should be rare exceptions, not the rule.

Tinted lenses should not be worn indoors under properly placed artificial light and never outdoors at night. They are dangerous for night driving; the glare of an automobile headlight is due to the contrast with the surrounding darkness, and no type of tinted glass can change that. The sense of ocular fatigue after day driving is more often due to uncorrected or improperly corrected errors of refraction or of muscle balance than to the bright light.

Despite the fantastic, absurd and untrue claims of the manufacturers of certain tinted glasses, the lighter shades of colored glass—tints that are hardly perceptible—offer little more protection against glare than clear glass. Nevertheless, promoters assert that through their miracle glasses the light is soft, cool and restful, as in a cathedral; work, they claim, is done more efficiently and with greater comfort. These hyperphysical lenses are said to match the complexion; to be inconspicuous yet improve the appearance; even to increase the visual acuity somehow or other; to protect the eyes against the ultraviolet and infrared in daylight, against amounts of energy which no one except the exploiters of these glasses would ever consider harmful; to keep out most of the light which seems to be bad light and let in only the good light. Through these glasses they claim, there are no annoying color disturbances—the makers have produced the impossible, a colored glass without selectivity. They show pictures of persons reading through their wonderful lenses by the light of a lamp in an otherwise dark room—a spotlight; suggesting that inadequate or poorly distributed artificial light is all right if you wear the right tint.

From Fitzsimons General Hospital.

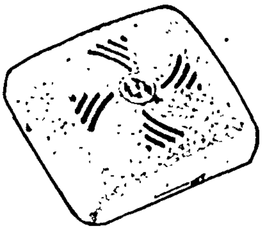
[1] Farrington, et al. Streptomycin Toxicity, J. A. M. A. **134:** 679-688 (June 21) 1947. A Preliminary Statement Concerning the Effects of Streptomycin Upon Tuberculosis in Man, manuscript prepared by the Surgeons General of the Army, Navy, and Veterans' Administration, July 3, 1947

The exploiters of these glasses would have the ophthalmologist consider a tint as a component of every lens he prescribes. This means that for the "visual comfort" of his patient the ophthalmologist would have to order a different shade for every intensity of light indoors and out. The patient would need a photometer and a bag full of tinted spectacles to meet what they suggest as requirements for proper vision.

AUREX HEARING AID, MODEL H, ACCEPTABLE

Manufacturer: Aurex Corporation, 1117 North Franklin Street, Chicago 10.

This is a plastic cased hearing aid, with separate batteries. The crystal receiver supplied has the Aurex trademark and is connected to the amplifier by a plastic covered cord (plugs at both ends). A four conductor battery cord connects to the batteries used.



Aurex hearing aid, model H.

One sliding type control on the side of the case serves as the switch and volume control. A rotating fan-type shutter may be turned from the center front of the case to close the microphone openings and serves as a partial tone control.

Dimensions and Weight

Dimensions: 70 by 63 by 22 mm. (2¾ by 2½ by ⅞ inch). Weight: Unit alone, approximately. 92 Gm. (3¼ ounces). With batteries, approximately 269 Gm. (9½ ounces).

Battery data		Voltage	Current
A 1½ volts	....	1.4 volts	55.0 milliamperes
B 30 volts	(Quiet)......	29 volts	0.6 milliampere
	(Squealing)..	29 volts	1.0 milliampere

Acoustical Gain

Measurements were made of the acoustical gain of the instrument in decibels. This is the decibel difference in sound pressure between the pressure at the face of the microphone opening (with the instrument set in a 16 by 8 inch, 40.6 by 20.3 cm., baffle) and the sound pressure produced by the receiver in a 2 cc. coupler. The microphone sound pressure was held at a level of 40 decibels over 0.0002 dyne per square centimeter. Typical results, obtained with the volume control full on and the tone control shutter open, are here tabulated for seven frequencies.

Frequency (cycles) ..	256	512	1,024	1,200	2,250	3,100	4,096
Gain in decibels.......	53	56	69	63	55	34	42

Maximum Output Pressure

Measurements were made of the approximate maximum sound pressure the instrument would produce in the 2 cc. coupler with the instrument set for full gain and shutter open. Levels are in decibels relative to 0.0002 dyne per square centimeter.

Frequency	Input Level	Maximum Output Level
600 cycles	55 decibels	103 decibels
1,024 cycles	55 decibels	113 decibels
2,048 cycles	60 decibels	104 decibels

Intelligibility Tests

Intelligibility tests (random words) were made with a person of normal hearing seated inside a booth giving about 30 decibels sound reduction. The speaking person was outside the booth using a normal tone of voice. The score made under these critical conditions was 48 per cent. These conditions are severer than tests using a deafened observer, because any internal instrument noise causes a lower signal to noise ratio due to the lower threshold of the person with normal hearing.

The Council on Physical Medicine voted to include the Aurex Hearing Aid, Model H, in the list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., *Secretary.*

ISOBORNYL THIOCYANOACETATE-TECHNICAL.—$C_{13}H_{19}N_2OS$.—M. W. 253.35. The technical grade of isobornyl thiocyanoacetate contains 82 per cent or more of isobornyl thiocyanoacetate with other terpenes.

Actions and Uses.—Isobornyl thiocyanoacetate is one of the thiocyanates shown to be effective as a pediculicide. A mixture of the technical grade of this compound with dioctyl sodium sulfosuccinate in the form of an oil emulsion is useful for external application to eradicate both the adult and ova forms of Phthirius pubis, Pediculus humanus capitis and Pediculus humanus corporis. Skin irritation studies reveal that the compound may act as a mild primary irritant to the skin of some persons, but there is no evidence that it acts as a sensitizing agent. It should not be applied too close to the eyes or to mucous membranes.

Dosage.—An oil emulsion containing isobornyl thiocyanoacetate—technical 5 per cent dioctyl sodium sulfosuccinate 0.6 per cent is applied externally in amounts of 30 to 60 cc. depending on the site involved (quantity of hair), worked into a lather and allowed to remain for from five to ten minutes. In the case of the scalp, the hair is then combed and permitted to dry, and the emulsion is left on over night. The head is washed the following day. In the case of the pubis and other regions of the body, the emulsion is worked into a lather and then washed off with soap and water. Care must be taken that the emulsion does not remain in contact with the skin for too long. More than two such applications should be avoided.

Tests and Standards.—

Isobornyl thiocyanoacetate-technical occurs as a yellow, oily liquid, possessing a terpene-like odor. It is very soluble in alcohol, benzene, chloroform and ether; it is practically insoluble in water. The refractive index of isobornyl thiocyanoacetate-technical is 1512. Its specific gravity at 25 C. is 1.1465. The acid number is 1.19.

Add to about 25 mg. of isobornyl thiocyanoacetate-technical in a small beaker 5 cc. of twice normal alcoholic potassium hydroxide. Cover the beaker with a watchglass and warm on a hot plate for five minutes. Acidify one half of the solution with dilute sulfuric acid and add a few drops of ferric ammonium sulfate T.S.: a red color develops.

Add 1 cc. of 10 per cent ferrous sulfate T.S. to the other half of the solution and warm for another five minutes. Make the solution acid to litmus paper with diluted sulfuric acid: a blue color develops in the solution.

Add 1 cc. of twice normal alcoholic potassium hydroxide to 5 cc. of a 10 per cent alcoholic solution of isobornyl thiocyanoacetate-technical: a yellow color forms, which rapidly changes to deep orange.

Dissolve 10 Gm. of isobornyl thiocyanoacetate-technical in 25 cc. of a saturated solution of potassium in methanol hydroxide and reflux on the steam bath for two hours. Pour the solution into 500 cc. of saturated sodium chloride solution and then acidify with hydrochloric acid. Filter the precipitate on a Buchner funnel, wash with saturated sodium chloride solution and air-dry on the filter. Dissolve the precipitate in petroleum ether, add 20 Gm. of anhydrous sodium sulfate, stopper and let stand for several hours. Filter, then evaporate the filtrate to a small volume and cool in an ice bath to effect crystallization. Filter off the crystals, wash with a few cubic centimeters of cold petroleum ether and air-dry: the isolated isoborneol melts from 200 to 205 C.

Determine the nitrogen content of isobornyl thiocyanoacetate-technical by the Kjeldahl procedure: the amount of nitrogen found is not less than 4.6 per cent, which is equivalent to an isobornyl thiocyanoacetate content of 80 per cent.

ISOBORNYL THIOCYANOACETATE LOTION

Pipet 10 cc. of bornate lotion into a graduated 100 cc. separatory funnel. Add 50 cc. of ether and shake vigorously. Add 10 cc. of ethanol and shake the contents of the flask to break the gel. Allow the funnel to stand and then draw off the lower layer. Dilute the solution in the separatory funnel to 100 cc. with ethanol. Transfer a 10 cc. aliquot to a Kjeldahl flask and determine its nitrogen content: the amount of isobornyl thiocyanoacetate-technical is not less than 90 per cent and not more than 110 per cent of the claimed amount.

WYETH INCORPORATED, PHILADELPHIA 3

Lotion Bornate: 60 cc. and 3.785 liter bottles. An emulsion containing isobornyl thiocyanoacetate 5 per cent, dioctyl sodium sulfosuccinate 0.6 per cent in mineral oil 5 per cent, gelatin 0.6 per cent and water.

JOHNSON & JOHNSON, NEW BRUNSWICK, N. J.

Hemo-Pak Absorbable Gauze Packing Strip (4 ply): 2 by 14 inches (5.08 by 35.56 cc.) and ½ inch by 2½ yards (1.27 by 228.6 cc.) in sealed tubes.

Hemo-Pak Absorbable Cotton Pad: 2 by 6 inches (5.08 by 15.24 cc.) in sealed tubes.

U. S. trademark registration pending.

Because of the continued absence of the compositors from work in the printing department, the index for volume No. 136 of THE JOURNAL will be published later.

VISUAL TRAINING FOR MYOPIA

In 1920 William H. Bates published a book, "Perfect Sight Without Glasses," in which he advanced the hypothesis that visual derangements and refractive errors are due to a deformation of the eyeball resulting from a nervous and muscular strain from the superior and inferior oblique muscles and that the ciliary muscle has nothing to do with focusing the eye. He developed a corrective treatment consisting of eye exercises described as "blinking," "winking," "nose reading," "palming" and "sunning." Established clinical and scientific observations do not support the Bates thesis. Lancaster[1] felt, however, that "buried in a mass of what to the ophthalmologists seem foolish gestures and performances, there are sound and fruitful ideas." Since seeing is only half ocular, according to Lancaster's statement, the other half being cerebral, repetition, practice and exercise are capable of building up a substratum of memories useful for the interpretation of sensation and formation of syntheses which are the larger part of seeing. Duke-Elder[2] pointed out in his review of Huxley's "The Art of Seeing" that visual defects are sometimes muscular in origin, sometimes pyschologic. The competent ophthalmologist treats the former with curative exercises, while the pyschologic approach is used for the mental aspect.

From the Wilmer Ophthalmological Institute of the Johns Hopkins Hospital and University comes a report on the results obtained in the treatment of myopia by visual training. According to Alan C. Woods,[3] 103 myopic persons were subjected, after preliminary examination, by a group of optometrists and psychologists to a course of visual training designed to improve their uncorrected vision. Improvement was noted in 30 of the group (29 per cent). It was considered that the improvement was due to education in the correct interpretation of a blurred visual image. In some of the patients exercises produced a beneficial psychologic reaction toward their visual handicap, regardless of whether an actual improvement in visual acuity had occurred. With the possible exceptions of educating some patients to interpret blurred retinal images more carefully and of convincing some others that they could see better even though there was no actual improvement, this study indicates that the visual training used on these patients was of no value for the treatment of myopia.

A similar study carried out by Hildreth[4] and co-workers at the department of ophthalmology of the Washington University and the Oscar Johnson Institute brought forth the following observation and conclusions: Fifty-four selected patients with myopia were given a course of visual training which was preceded and followed by a complete ophthalmologic examination. The training was given by an optometrist while the pretraining and post-training examinations were made by a group of ophthalmologists. Thirty of the patients showed no change in their acuity, while 12 manifested a definite improvement, the best results being obtained in the subjects with low degrees of myopia. Twelve patients showed a change so slight as to be excluded in the results. The change in the improved group averaged 27 per cent. There was no change in the refractive error and no significant alteration in the ocular neuromuscular mechanism. The improvement, it was believed, probably occurred because of an improvement in reception due to stimulation of the visual effort, as the best results occurred in those patients whose pretraining acuity was less than would be expected from their refractive error. It was considered that visual training has a definite but limited value in some myopic patients, predominantly in those whose vision does not correspond with their known myopia.

Visual training merits further study from the ophthalmologists, particularly in relation to progress in myopia. However, the careful scientific studies that have been made now prove that the slogan "Throw away your glasses and have perfect sight" is a dangerous suggestion. The benefits from muscular training alone are a minimal aid in the proper assisttance to faulty vision.

Current Comment

MEDICAL EDUCATION IN PUERTO RICO

Puerto Rico does not have a medical school. Unquestionably Puerto Rico suffers from a shortage of physicians and particularly from a shortage of competent physicians. As was pointed out by the commission headed by Dr. Ernest E. Irons which visited Puerto Rico recently, the Puerto Rican government arranged for the admission of a number of physicians who could not meet the standards of North American licensing boards or of the Council on Medical Education and Hospitals of the American Medical Association. Those who promoted this procedure argued that these physicians would locate in the rural areas and small towns and thus make available medical service to persons who could not secure it. Actually, many of these physicians drifted promptly into the larger cities and proved again that economic factors involved in determining the location of physicians for practice dominate other considerations. Now the proposal has been made by a group of Polish physicians associated during the war with the University of Edinburgh, which made available to them its laboratory facilities for the establishment of a medical school in which medicine was taught in Polish, to move the institution to Puerto Rico and organize a medical school along European lines with funds which are promised from the so-called Paderewski Foundation. Reports say that some $4,000,000 are available for the purpose. Whether such a project could succeed is extremely doubtful. Medical schools are not made in a day or a night. The quality of the faculty is dependent on its ability to secure competent teachers in the basic sciences and clinical teachers of experience in sufficient numbers to give individual instruction to prospective physicians. Since the proposed faculty did most of its teaching in Polish while resident in Edinburgh, some doubt arises as to the ability of the same faculty to teach successfully in either English or Spanish, should they become established in Puerto Pico. Certainly before any positive action is taken a most thorough investigation should be made as to the medical educational standards to be followed, since the organization of a medical school of less than a minimum standard for medical education that prevails in the United States would be a wasteful expenditure of time, energy and foundation. In the meantime through proper cooperation between leaders of medicine in Puerto Rico and those in the United States increasing efforts should be made to accommodate from thirty to fifty young properly qualified Puerto Rican students annually in the medical schools of the United States.

BIOLOGIC AVAILABILITY OF PROTEIN

A new procedure for measuring the biologic availability of proteins consists in removing surgically about 70 per cent of the liver of rats previously fed a high calory , protein-free diet and measuring the replacement of this liver protein during a recovery phase.[1] Some replacement of liver protein occurs even on a protein-free diet as the result of mobilization of tissue proteins. Feeding gelatin and zein lead to no more regeneration of protein than does the nonprotein diet. Wheat gluten gives a moderate increase, liver protein and casein a larger increase; fibrin and whole egg protein result in the greatest increase in liver protein regeneration. The results confirm those obtained by the nitrogen balance method.

TUBULAR REABSORPTION OF INORGANIC SULFATE

The ability of the kidney tubules to reabsorb normal levels of essential constituents of plasma and to allow excess amounts to pass on into the urine constitutes a principal mechanism for the control of the blood level of these substances. Waste products do not show so definite a threshold; in the case of creatinine, none is reabsorbed and all that is filtered through the glomerulus passes into the urine. A recent study[1] of the excretion of sulfate reveals that this substance has a sharp renal threshold at a level which corresponds to the normal concentration in plasma. At higher plasma levels, the tubular reabsorption remains constant and excess sulfate is excreted. The existence of this threshold would seem to suggest that the small amount of sulfate in the blood, which has heretofore been considered to be simply excretory, plays some metabolic role.

Debate Cause of Shortage of Physicians in Maryland

A Cumberland County general practitioner has squared off with the members of the medical profession in Maryland over the reason for the shortage of physicians. Dr. Charles S. Maxon, president of the Medical and Chirurgical Faculty of Maryland, the State Association of Physicians and Surgeons, said that it is harder to get the services of a physician because, among other things: patients abuse physicians by calling them at all hours over minor aches and pains; physicians like the forty hour week, and medical schools turn out too many specialists and not enough general practitioners. Dr. Richard J. Williams of Cumberland County took issue with views of Dr. Maxon and declared that " unless you men at the top speedily mend your ways and stop trying to shift the responsibility onto the shoulders of the few of us who are doing general medicine, then the public will rise up and give us state medicine whether we like it or not."

Chest X-Ray Drive Going Down Embassy Row

Foreign embassies are cooperating in the national chest x-ray drive now being conducted throughout the country. A survey machine paid its first visit to the Chinese Embassy in a series of stops that will include the whole diplomatic corps. A portable x-ray machine will visit the British Embassy for examination of Lord Inverchapel, retiring ambassador, and members of the staff and their families. Australia, New Zealand and the Union of South Africa are next on the list, to be followed by sixty-five other embassies, legations and missions.

Study Use of Penicillin to Prevent Infant Blindness

Dr. Joseph S. Spoto, senior surgeon in the Venereal Disease Division of the U. S. Public Health Service, said preliminary studies reveal that penicillin may be a safer and more effective substance than silver nitrate to prevent blindness among newborn infants. He disclosed in a letter to Representative Huber, Democrat of Ohio, that the use of penicillin for this purpose is now under test. He explained that penicillin can be applied either by eye droppers as with silver nitrate or by treating the mother with the drug several days before the birth of the child. Laws of most states now require that a mild solution of silver nitrate be applied to an infant's eyes as a protection against infection.

Senators Testify for Heart Institute Bill

Senators of opposite political allegiance testified in support of a bill to establish a National Heart Institute under the U. S. Public Health Service, a bill which is sponsored by Senators Bridges and Ives, Republicans, and Senators Pepper and Murray, Democrats. In addition to Bridges and Pepper, witnesses included interested members of the House of Representatives and Federal Security Administrator Oscar R. Ewing, who declared that " The extension of Federal aid for heart disease research and control is indispensible to any coordinated, large scale attack on the problem." The bill would also authorize the Surgeon General to conduct and foster research, provide grants to universities, hospitals and other agencies for heart disease study and establish research fellowships at the institute and elsewhere. Also proposed is a national Heart Council to advise the Surgeon General and authorize him to make grants in aid to states and other agencies for prevention, diagnosis and treatment of heart disease. Surgeon General Leonard E. Scheele, of the Public Health Service, and representatives of the American Heart Association also testified.

Dr. John R. Heller Heads National Cancer Institute

Dr. John R. Heller, former head of the Venereal Disease Division of the U. S. Public Health Service has been appointed director of the National Cancer Institute of Bethesda, Md. He succeeds Dr. Leonard A. Scheele, who has been appointed Surgeon General of the U. S. Public Health Service. Dr. Heller will supervise the federal cancer program, including research conducted at Bethesda laboratories, research grants to other laboratories and hospitals, and federal aid in teaching and cancer control work.

Mrs. Meyer Urges Revamping of Nation's Social Agencies

Mrs. Eugene Meyer, wife of the chairman of the board of the *Washington Post*, told a local group that there is need for cooperation of social agencies and a united effort to coordinate the nation's "cluttered community services." She criticized Dr. Alfred C. Kinsey's "Sexual Behavior of the Human Male "as a flagrant misuse of the scientific method.

Medical Legislation

Mississippi

Bill Enacted.—H.386 was approved March 23. It provides for the appropriation of $510,000 to the state medical education board for the purpose of carrying out the provisions of the law relating to medical scholarships and loans.

New Jersey

Bill Enacted.—S.J.R.5 has become Joint Resolution No.2 of the Laws of 1948. It designates the month of April as Cancer Control Month throughout the state of New Jersey and urges citizens thereof to give support to the American Cancer Society and its cancer control program.

New York

Bill Enacted.—S.2524 has become chapter 695 of the Laws of 1948. It provides for the establishment of a state university and directs such state university to formulate plans and make recommendations for the establishment of two health and medical centers as a part thereof.

South Carolina

Bill Enacted.—H.1457 has become Governor's Act No. 798 of the Acts of 1948. It authorizes the acquisition of land for a site for a teaching hospital in the city of Charleston for use by the Medical College of South Carolina.

Virginia

Bills Enacted.—H.439 was approved April 1, 1948. It requires every practicing medical doctor to obtain a revenue license.

S.177 was approved April 1. To amend the hospital lien law, it increases the extent of such lien in favor of hospitals and physicians.

GOVERNMENT SERVICES

ARMY

PROGRAM FOR RESERVE OFFICERS

A committee of scientists and engineers who hold commissions in the Organized Reserve Corps met at the Pentagon Building March 26-27 to consider the Army's proposed research and development reserve program. The committee approved the contemplated program and recommended its immediate establishment; it recommended also procedures for optimum use of the technologic skills of all reserve officers engaged in the medical, biologic, physical and engineering sciences. With Brig. Gen. Norman W. Lack of Wilmington, Del., as chairman, the committee included representatives of various aspects of research, both governmental and industrial, scientific societies and educational institutions.

Under the proposed program, reserve officers who are professional scientists would be enabled to pool their knowledge for concentrated attack on Army research and development problems; it is contemplated that the program will result in effective mobilization assignments for key scientists to insure rapid mobilization in event of emergency. The first of the research and development reserve groups formed under this program was established in Wilmington, Del., in 1947 under the leadership of Brig. Gen. Lack. Similar units are being established in Philadelphia and Urbana, Ill. When the program has been approved, it is anticipated that similar groups will be instituted throughout the country.

NEW ASSIGNMENTS IN SURGEON GENERAL'S OFFICE

The Surgeon General's Office announces the following new assignments: Col. Clifford G. Blitch, chief, Medical Consultants Division; Lieut. Col. Otis W. Snyder, office of the chief, Personnel Division; Major Kenneth E. Ranson, chief of the Enlisted Branch, Personnel Division; Major Marion C. Stith, executive officer of the Hospital Division; Major William J. Clegg Jr., chief of the Administrative Branch, Hospital Division; Capt. Ula M. Morgan, assistant chief, Hospital Standards and Inspection Branch, Hospital Division, and Capt. Joseph D. Nolan, chief, Medical Regulating Branch, Hospital Division.

MEDICAL MEETING IN KOREA

About sixty officers of the medical department attended the monthly meeting at the 377th Station Hospital in Korea on March 24, at which the hospital commandant, Col. Herbert J. Witt, M.C., presided at the afternoon session. A symposium was presented on Korean medical education in which Capt. J. Richard Compton, M.C., chief of medical service at the hospital, discussed "Korean Medical Education Under New Influences"; Mildred Barody, R.N., Department of Labor, "Experiences in Organizing Industrial Medical Care"; Capt. Irwin L. Selvage Jr., M.C., "Roentgenologic Methods and Results"; Dr. Keum S. Sohn, director, Seoul Red Cross Hospital and chairman of the board of trustees, Korean Medical Association, "Current Problems in Hospital Management," and Lieut. Morton Palken, M.C., "Exigencies of a Surgical Practice Under Economic Stress." In the morning a case of kala-azar in a Korean refugee was presented, also papers on "Hospital Supply Procedures" by Capt. Louis J. Chaput, M.S.C., and "Reports of Surveys" by Capt. James O. Darling. Following a business meeting at which Col. Charles P. Ward, 24th corps surgeon, presided, a buffet supper was served at the Nan San Hotel.

ARMY INSTITUTE OF PATHOLOGY

Dr. Arthur T. Hertig, assistant professor of obstetrics, Harvard Medical School, Boston, discussed "Human Development in Its Earliest Stages" before the staff of the Institute in Washington, D.C., March 24.

Dr. Hans F. Smetana of the Institute of Pathology talked on "Periarteritis Nodosa Medionecrosis and Dissecting Aneurysms" at George Washington University School of Medicine March 19.

During April the institute held exhibits at the following places: annual meeting of Ohio State Medical Association, Cleveland; American Association for Health and Physical Education, Kansas City, Mo.; celebration of Army Week, Boston, and at the annual meeting of the National Conference of Social Workers, Atlantic City, N. J.

AIR FORCE

N.R.C. COMMITTEE VISITS RANDOLPH FIELD

The committee on Aviation Medicine of the Division of Medical Sciences, National Research Council, visited the Air University School of Aviation Medicine, Randolph Field, Texas, April 3 to review its research activities and to hold a seminar on a specific phase of aviation medicine.

Among the visitors were: Dr. Detlev W. Bronk, Johnson Research Foundation, University of Pennsylvania, (chairman); Dr. Wallace O. Fenn, University of Rochester, Rochester, New York; Dr. John C. Flannagan, University of Pittsburgh; Dr. H.K. Hartline, University of Pennyslvania, Philadelphia; Dr. George L. Maison, Boston University School of Medicine; Dr. Craig L. Taylor, University of Southern California, Los Angeles, and Dr. E. J Baldes, Mayo Clinic Aero-Medical Unit, Rochester, N. Y.

Accompanying the scientists were: Col. O.O. Benson Jr., Chief of Research, Air Surgeon's Office; Capt. Winfred P. Dana, research director, Bureau of Medicine and Surgery, Washington, D.C.; Wing Comdr. B.R. Brown, Institute of Aviation Medicine, Toronto, Canada, and Wing Comdr. J.H. Neal, Medical Air Attache, British Embassy, Washington, D.C.

SPECIAL RESEARCH POSITION OPEN

The Air University School of Aviation Medicine, Randolph Field, Texas, is in receipt of an announcement from Headquarters, U.S. Air Force, that the school has been allotted one of a limited number of special research positions authorized by Congress to attract outstanding scientists to service laboratories. The School of Aviation Medicine intends to utilize the new allocation, which carries with it a salary of $10,000 to $15,000 per annum, to establish a civilian position for a director of research. Inquiries concerning this vacancy should be addressed to the commandant.

NAVY

MEDICAL OFFICERS CERTIFIED BY BOARDS

The Bureau of Medicine and Surgery announces that as of March 30, one hundred and thirty-nine medical officers of the Regular Navy have been certified by American specialty boards, and that two hundred and five medical officers had completed graduate training courses of six months to one year's duration in various specialties during 1947. Of this number, eighty-seven were trained in civilian institutions and one hundred and eighteen in naval hospitals. Additional medical officers will be eligible for examinations by specialty boards within the next few months.

PLAN ADDITIONAL RESERVE MEDICAL DIVISIONS

A new organization plan for inactive volunteer reserve units of the Navy Medical Corps, which provides for the formation of two hundred and forty reserve medical divisions throughout continental United States, has been placed in effect. To date one hundred and forty-four reserve medical divisions have been organized in the eleven continental Naval Districts and the Potomac River Naval Command. Members of the inactive volunteer reserve are assigned to the individual medical division in accordance with their professional qualifications. Their assignment, however, carries no additional obligations or responsibilities other than those which the members are willing to assume. The new plan permits the administration of a training program for inactive reservists, including medical division meetings at which qualified instructors present subjects peculiar to military medicine; in addition, special training courses on some of the subjects may be arranged.

THE SURGEON GENERAL'S SYMPOSIUM

The symposium of the Surgeon General with all district medical officers, medical officers in command of naval hospitals and other medical activities will be held at Bethesda, Md., May 27-29. The subjects discussed will include the organization of the Bureau of Medicine and Surgery, the graduate training program, formation of reserve divisions, modernization of equipment in naval hospitals, medical aspects of atomic energy, procurement and personnel, planning and logistics. In addition to naval officers, the speakers will include the Honorable John L. Sullivan, Secretary of the Navy, and Dr. Henry L. Bockus of Philadelphia.

NEW REGULAR OFFICERS

The following physicians have been commissioned in the Medical Corps of the Regular Navy: Comdr. LeRoy E. Wible, Albuquerque, N.Mex., and Lieut. John T. Egan Jr., Jamaica, N.Y.

The following graduates of the Navy's V-12 program have accepted commissions in the Regular Navy Medical Corps: Lieuts.(jg) John P. Ahearn, Somerville, Mass.; Carleton J. Brown, New London, Conn.; Robert J. Evoy, Seattle; Arthur A. Helgerson, Attleboro, Mass.; James H. Lee Jr., Wilmington, Del.; Joseph E. F. Rankin, Baltimore; Myron E. Samuelson, Genoa, Neb., and Julius H. Spence, Austin, Texas.

VETERANS ADMINISTRATION

MEDICAL ADMINISTRATIVE OFFICERS WANTED

The U. S. Civil Service Commission is accepting applications to fill high level administrative positions with the Veterans Administration in the field of medical administration. These positions are open in the central office of the Veterans Administration in Washington, D. C., and in branch offices and hospitals throughout the country. The salaries range from $7,102 to $9,975 a year. In the central office the duties of these positions are in part as follows: developing policy, determining methods and supervising such administrative activities of veterans' hospitals and national homes as admissions, discharges, transfers and food requirements. In the branch offices the duties are to supervise the program for medical administration and to coordinate it in centers, hospitals, homes and regional offices of the branch area. In the veterans' hospitals the duties of these positions are to coordinate and direct the activities of hospitals within the scope prescribed by the deputy administrator or the Department of Medicine and Surgery, by formulating and executing local policies and by carrying out plans issued by higher authorities; also, to administer the medical activities of the hospital through the chief medical officer.

Applicants must be citizens of or owe allegiance to the United States, or be citizens of the Republic of the Philippines. Applications should be made on circular EC-11, which shows the administrative experience requirements for these positions. Persons interested should apply not later than April 14, 1948 to the U. S. Civil Service Commission, Washington, D. C.

HOSPITAL CONSTRUCTION AT NEW HIGH

Lieut. Gen. Raymond A. Wheeler, chief of Army engineers, announces that twenty-three veterans' hospitals are now under construction and when completed will provide an additional 10,386 beds. During the first quarter of 1948 contracts were let for twelve general hospitals and bids on two additional hospitals were advertised. In addition, forty-six hospitals are still in the process of design; forty others have progressed sufficiently to be scheduled for advertising. During the present year the five hospitals which have not yet been scheduled for advertising include the six hundred bed tumor clinic in Chicago and four general hospitals to be constructed in Boston, New York, Syracuse and Washington, D.C. Of seventy-one hospitals scheduled for construction by the Corps of Engineers under the Veterans Administration program, five had been designed by the Agency prior to the engineers' participation in the program. General Wheeler also announced that contracts had been awarded for the nine hundred and ninety-nine bed hospital in Albany, N.Y. The total amount of the six contracts involved is $14,445,727. Construction progress on the Veterans Administration hospital program has doubled that of last year, General Wheeler said. The increased construction costs necessitated the redesigning of practically all hospitals that had not been actually placed under contract.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

CALIFORNIA

Medical Garden Club Show:—The Los Angeles County Medical Garden Club will present the regular Spring Flower Show in the lounge of the Los Angeles County Medical Association headquarters building on April 29-30. This show will be opened to the public without admission charge April 19 from 12 noon to 9 p.m. and Friday, April 30, from 9 a.m. to 9 p.m. Entries will be accepted from doctors of medicine. Flower arrangements only may be entered by the wives of physicians. and members of the physicians office personnel.

COLORADO

Laboratories Approved for Blood Tests.—The state department of public health has approved twenty-two laboratories in Colorado to perform premarital and prenatal blood tests. Their certificates of approval will expire Dec. 31, 1948 but may be renewed. These laboratories were required to pass inspection. Each received two hundred blood specimens and was required to obtain an average of not less than 99 per cent correct results on the nonsyphilitic specimens and not less than 90 per cent on the syphilitic specimens as compared with the results of the control laboratories. Clerks in marriage license bureaus have been instructed to accept blood tests only from approved laboratories , a list of which may be secured by writing Marjorie Van Vranken, Secretary, Evaluation Committee, 430 State Office Building, Denver.

State Health Department Reorganizes.—In the recent reorganization of the Colorado State Department of Public Health all sections dealing with medical care and services have been put under a director of Preventive Medicine Services. Those sections whose activities are used by all other units in the department, such as administration, health education, records and laboratories, have been placed in the Division of General Services, thus eliminating the need for their duplication in various sections. All sanitation activities will be under the direction of the Division of Sanitary Services. Three new services under full time directors have been added: health education, hospital facilities and veterinary medicine. Increased budget and personnel have made it possible to provide more service to local areas in the form of consultation and advisory visits on both old and new programs and to begin services which previously had not been available.

CONNECTICUT

Memorial to D. Chester Brown.—A gift of several thousand dollars has been contributed to the building fund of the Connecticut State Medical Society by the friends and patients of the late Dr. D. Chester Brown. Dr. Brown was a trustee of the American Medical Association from 1918 to 1930. He was president of the Connecticut State Medical Society in 1913 and president of the Fairfield County Medical Association in 1908.

New Medical Building in Hartford.—Construction of an eight story medical building to provide suites of offices for about ninety physicians was recently begun in Hartford. The building is being erected by the Connecticut Mutual Life Insurance Company adjacent to the new addition to the Hartford Hospital.

ILLINOIS

Nursing Homes.—The state department of public health has licensed two hundred and twenty-two nursing homes and exercises supervision over them. Peoria County heads the list with 565 beds. Cook County, outside Chicago, has twenty-one nursing homes with a bed capacity of 1,144. A directory of all nursing homes in Illinois that are licensed by the Illinois State Department of Public Health is available on request to the department's Division of Sanitary Engineering, Springfield.

Chicago

Goodspeed Memorial Fund.—The Charles B. Goodspeed Memorial Fund has been started in memory of the late former president and benefactor of Presbyterian Hospital. Other friends of Mr. Goodspeed are being invited to join with staff contributors in providing the fund. Drs. William G. Hibbs and Harry Boysen comprise the medical staff committee in charge of the project. Checks made payable to Presbyterian Hospital and designated for the Goodspeed Memorial Fund may be sent to the committee. Pledges payable over a period of five years also are sought.

INDIANA

New Section Created.—A section on obstetrics and gynecology of the Indiana State Medical Association has been organized with Dr. Dudley A. Pfaff, Indianapolis, chairman, and Dr. Edgar L. Engel, Evansville, secretary.

Medical Alumni Day.—The first Alumni Day of the Indiana University School of Medicine will be held on the Medical Center campus in Indianapolis on May 5, also Founders Day of the university. A clinical program will be held in the auditorium of the medical school from 9:30 to noon. Luncheon at 1p.m. will be followed by a general session at 2 p.m.

IOWA

State Journal Dedicated to Dr. MacEwen.—The April issue of the *Journal of the Iowa State Medical Society* has been designated the Dean MacEwen Memorial Issue and contains articles contributed by the staff of the State University of Iowa College of Medicine, where Dr. Ewen M. MacEwen served as dean from 1935 to 1947. Problems of medical education, research and hospitals are discussed in the issue.

MAINE

Dr. Crosby Honored.—More than three hundred and fifty townspeople of Milo honored Dr. Nathaniel Crosby at a town hall meeting February 23, on the occasion of his eighty-fourth birthday and his fifty-seventh year of service as a physician. The Rotary Club of Bangor shared in the proceedings, and the Maine Medical Association sent greetings. Many tributes were paid to Doctor Crosby for his years as a general practitioner.

MASSACHUSETTS

Harvard Increases Tuition.—An increase in tuition for all students at Harvard Medical School and Harvard University Dental School, Boston, was announced April 5. Tuition in both schools, which has been $580 a year since 1945, will be raised to $800 a year beginning in the fall term of 1948. Officers of the two schools assured students that loan funds and scholarships are at hand to assist individuals in meeting the increased cost. Additional scholarship funds will be available next autumn.

MINNESOTA

Personal.—Charles Sheard, Ph.D., Director, Division of Physics and Biophysical Research, Mayo Clinic, Rochester, Minn., was guest of honor at a dinner in Washington, D.C., March 11, at which Surgeon General Clifford A. Swanson, U.S. Navy, and representatives Dewey Short of Missouri and Arthur L. Miller of Nebraska were among the speakers.

Public Health Nursing Services.--Since the passage a year ago of the state law subsidizing public health nursing, eleven counties of Minnesota have established public health nursing services and eight have taken advantage of the subsidy provisions to employ additional nurses. The state now has four hundred and sixty-four public health nurses, about equally divided between large cities and rural areas.

NEBRASKA

Dedicate Childrens Memorial Hospital.—The dedication in Omaha of the Childrens Memorial Hospital was held in February. According to newspaper reports more than 30,000 persons from Nebraska and surrounding states contributed to the hospital fund. The hospital adds more than one hundred beds for the treatment of children and will make available improved facilities for study and research in growth and development. The combined staffs of Creighton University School of Medicine and University of Nebraska College of Medicine make up the medical organization of the hospital.

NEW JERSEY

Annual State Medical Meeting.—The Medical Society of New Jersey will hold its annual meeting at Haddon Hall, Atlantic City, April 26-29. The program is made up largely of section meetings in which members of the society and guest speakers will take part. At the general session Wednesday afternoon, Mr. Arthur L. Conrad, Chicago, will speak on "Implications of Socialized Medicine" and Dr. Isidore Snapper, New York, on "Medicine Is Global." The dinner dance will be Wednesday at 7:30 p.m. The guest speaker will be John C. Krantz Jr., Ph.D., Baltimore, 'The Simplicity to Wonder." Scientific, educational and technical exhibits have been arranged. The Woman's Auxiliary will meet in conjunction with the state society.

NEW YORK

Postgraduate Lectures.—The following postgraduate lectures have been arranged by the Medical Society of the State of New York in cooperation with the New York State Department of Health:

Sullivan County Medical Society

April 21 George P. Heckel, Rochester, Practical Application of Endocrines in Gynecology, Workmen's Circle Sanatorium, Liberty, 8:30 p.m.
April 28 Clyde L. Randall, Buffalo, Office Management of Female Pelvic Disorders, Lenape Hotel, Liberty, 8:30 p.m.
May 5 Ferdinand J. Schoeneck, Syracuse, Sterility, Monticello Hospital, Monticello, 8:30 p.m.
May 12 Chester E. Clark, Syracuse, Gynecology in General Practice, home of Dr. Harry Golembe, Liberty, 8:30 p.m.

Nassau County Medical Society

April 27 A. W. Martin Marino, Brooklyn, Early Diagnosis of Cancer of Rectum, Garden City Hotel, Garden City, Long Island, 9:00 p.m.
May 25 Robert M. Marcussen, New York, Treatment of Migraine, Cathedral House, Garden City, Long Island, 9:00 p.m.

The Ontario County Medical Society will hear Dr. Jacob D. Goldstein, Rochester, speak on diseases of the liver, at Canandaigua Hotel, Canandaigua, April 13, 8 p.m. On May 13 Dr. Richard S. Farr, Syracuse, will address the Jefferson County Medical Society at Hotel Woodruff, Watertown, 8:30 p.m., on treatment of low back pain.

PENNSYLVANIA

County Society to Honor Dr. Bortz.—A homecoming celebration in honor of Dr. Edward L. Bortz, Philadelphia, President of the American Medical Association and a native of Westmoreland County, is being sponsored by the Westmoreland County Medical Society on May 5-6. A public health meeting in the Greensburg High School Auditorium on May 5, 8:15 p.m., with Dr. Bortz speaking on "Health as Our Fundamental National Resource" will start the celebration. Others to speak at this public meeting will be: Dr. Norris W. Vaux, Philadelphia, secretary of health; Mr. Lester H. Perry, executive secretary of the state society; Dr. Chauncey L. Palmer, Pittsburgh, chairman of the Committee on Public Health Legislation; Dr. Oliver E. Turner, Pittsburgh, member of the commission on Public Health and Preventive Medicine; and Dr. Pascal F. Lucchesi, superintendent and medical director of Philadelphia General Hospital, Philadelphia. On Thursday, beginning at 10 a.m., an all scientific program will be held at the Westmoreland County Hospital Dr. Elmer Hess, Erie, president of the Medical Society of the State of Pennsylvania, will discuss "Urologic Hints for the General Practitioner." Six other specialists will appear on the morning program. Speakers at the session to be held at the Greensburg Country Club will be:

Dr. James E. Paullin, Atlanta, Ga., Peptic Ulcer, Pathogenesis and Medical Approach.
Dr. Waltman Walters, Rochester, Minn., Surgery in Peptic Ulcer.

Dr. Paullin will also talk on the "Management of Severe Diabetes" and Dr. Walters on "Advance in Treatment of Lesions of the Biliary Tract."

WISCONSIN

International College of Surgeons.—The Wisconsin Chapter of the International College of Surgeons will meet April 28 for a dinner at 6:15 p.m. and a scientific program at 8 p.m. at the University Club of Milwaukee. Papers to be presented are on the following topics: surgery of the rectosigmoid; diagnostic and therapeutic management of difficult surgical case; repair of large postoperative ventral hernia; fenestration operation for the improvement of hearing; high tension line injury--electric burns, and Wilm's tumor--case report.

GENERAL

Congress of German Internists.—Members of the American Medical Association are invited to attend the Congress of German Internists May 19-21 in Karlsruhe. An attendence of two thousand specialists in internal medicine is expected. Subjects to be discussed at the Congress are "The Vegetative Nervous System," "The Coloring Matter of the Blood" and "Virus Diseases."

Association for Study of Goiter.--The American Association for the Study of Goiter will meet at the King Edward Hotel, Toronto, Canada, May 6-8, under the presidency of Dr. James H. Means, Boston. Among the subjects of the guest speakers, will be the relationship of hyperthyroidism to myasthenia gravis; the hazards and limitations of radioactive isotopes; treatment of hyperthyroidism with radioactive iodine; effect of total thyroidectomy on the function of metastatic cancer of the thyroid, and the surgical treatment of the thyroid disease.

Psychiatrists Appoint Medical Director.—Dr. Daniel Blain, formerly chief of neuropsychiatric services for the Veterans Administration, has accepted the newly established position of medical director of the American Psychiatric Association. Dr. Blain will continue to reside in Washington, D. C. For the present he may be addressed at Georgetown University Hospital, Washington, D. C., or at the executive office of the association, Room 924, 9 Rockefeller Plaza, New York 20. Mr. Austin M. Davies, who has been with the association for fifteen years, will continue as executive secretary, with headquarters in the New York office.

Lippincott Library Award.--The American Library Association Committee on Awards announced that the Joseph W. Lippincott Award for Distinguished library service during 1947-1948 will be given at the association's conference in Atlantic City, N. J., June 13-19. It consists of a $500 gift and a certificate presented by the donor. Names of nominees should be submitted to John M. Cory, chairman, Americal Library Association Committee on Awards, University of California, Berkley, Calif., Mary N. Barton, Enoch Pratt Free Library, Baltimore, Md., or to Ola M. Wyeth, Savannah Public Library, Savannah, by May 15. The award was temporarily discontinued in 1941.

Symposium in Ophthalmology.—A refresher symposium in ophthalmology will be given by Mount Sinai Hospital in affiliation with Columbia University College of Physicians and Surgeons, April 26 - May 22. This will consist of clinical, laboratory and didactic instruction in pathology, embryology, bacteriology, optics, surgery, ophthalmoscopy and other subjects. The class will be limited to eight qualified ophthalmologists. Information may be obtained from the Registrar of Medical Instruction, Mount Sinai Hospital, New York, or from Dr. John B. Truslow, Assistant Deam, Columbia University College of Physicians and Surgeons, New York.

World Health Assembly.--The World Health Assembly, representative of all members of the World Health Organization, will be convened in Geneva, Switzerland, on June 24, under a recent decision made by the Interim Commission, officials of the State Department announce. At present, twenty-two members and eight nonmembers of the United Nations are parties to the constitution of the World Health Organization. As the constitution does not legally come into force until twenty-six members of the United Nations become parties to it, it is hoped that additional nations, including the United States, will join the organization prior to the assembly in June. If the assembly follows the recommendations made by the Interim Commission, the World Health Organization will focus its activities, during the early years on malaria, tuberculosis, venereal diseases, and maternal and child health.

Meeting of Tropical Medicine and Malaria.--The fourth International Congresses on Tropical Medicine and Malaria will be held in Washington, D.C., May 10-18 under the sponsorship of the Department of State. The last meeting of the congresses was in Amsterdam, Netherlands, in 1938. About twenty-five nations will send official delegations. Although no formal invitations have been sent to many of the medical, technical and scientific institutions, societies and organizations throughout the world, the Department of State welcomes all interested professional men and women, including students, to participate. Those who desire to attend should communicate with the Division of International Conferences, Department of State, as soon as possible. To facilitate the program, the meetings will be held in twelve sections as follows: Research and Teaching Institutes, Tropical Climate and Physiology, Bacterial and Spirochetal Diseases, Virus and Rickettsial Diseases, Malaria, Helminthic Diseases, Protozoan Diseases, Nutritional Diseases of the Tropics, Tropical Dermatology and Mycology, Tropical Veterinary Medicine, Public Health, and Medical and Veterinary Entomology. Two evening meetings will commemorate historic discoveries in tropical medicine. The first will celebrate the demonstration by Walter Reed of the mosquito transmission of yellow fever and his admission to the Hall of Fame. The second will commemorate the fiftieth anniversary of the discovery by Ronald Ross of the method of malaria transmission.

National Health Assembly--Oscar R. Ewing, Federal Security Administrator, had a meeting on March 16 of persons he selected to compose an executive committee for the National Health Assembly to be held May 1-4 in Washington, D. C. This committee suggested the number of sections which should compose the assembly and their titles, and agreed on some of the chairmen. The assembly will divide itself into the following fourteen sections: (1) Nation's Need for Medical and Health Personnel; (2) Nation's Need for Hospital Facilities, Health Centers and Diagnostic Clinics; (3) Local Health Units for the Nation; (4) Chronic Disease and the Aging Process; (5) Maternal and Child Health; (6) Rural Health; (7) Research in the Service of Health; (8) Medical Care; (9) State and Community Planning for Health; (10) Physical Medicine and Rehabilitation; (11) Dental Health; (12) Mental Health; (13) Environmental Sanitation, and (14) Nutrition in World Health. The executive committee also approved of a tentative statement of the scope of the sections. A chairman and a steering committee will be appointed for each section.

Mr. Ewing has since announced the formation of a research section of the forthcoming assembly. Dr. Andrew C. Ivy, vice president of the University of Illinois, will be chairman of the research section. While the broad area of the medical research problem will be outlined by Dr. Ivy and the committee preparatory to the convening of the assembly, the specific agenda of the section will not be formulated until its first session.

Dr. Hugh R. Leavell, professor of public health practice, Harvard University School of Public Health, will be chairman of the medical care section of the assembly. In announcing the formation of the section, Mr. Ewing stressed the importance of a thorough analysis of the problem of medical care in terms of need and existing services as they affect the patient, the physician, the hospital administrator and the public health official. Voluntary plans for financing medical care, he said, should be examined for their adequacy in terms of efficiency, quality and coverage of services, and costs within ability to pay

The environmental sanitation section of the assembly will have as chairman Arthur D. Weston, director of sanitary engineering, Massachusetts State Department of Public Health. This section will include leaders in public health and sanitary engineering; scientists in chemistry, biology and allied fields; representatives of milk and food producers, of industry and labor, and farm groups

CORRECTION

Hormonal Test for Fetal Death.--In THE JOURNAL, April 10, in the article by Zondek, Sulman and Black entitled "Hormonal Test for Fetal Death in Disturbed Pregnancy" in the eleventh line, page 968, the words 9 per cent should be 90 per cent.

Foreign Letters

ITALY

(From Our Regular Correspondent)

Feb. 1, 1948.

Meeting of Tuberculosis Association

The Sicilian Tuberculosis Association met in Catania to discuss reports presented by members. Professor Condorelli presented a synthesis of twenty years observation on Tuberculous peritonitis, Circumscribed discrete forms of tuberculous peritonitis were defined as mute. This referred only to syndromes caused by tuberculous and protopathic peritonitis, with mild dissemination, few general manifestations, chronic course and vague abdominal symptoms. Classic pathology was considered of little aid in study of this syndrome. Observations were made and laparotomy performed because of diagnostic errors in cases in which the clinical picture had not been outlined. The symptoms consist in mild rise of temperature. general malaise, variable anemia, and frequent disturbances of organic sensibility and the vegetative nervous system. Abdominal symptomatology is indefinite and consists of functional gastric disturbances and abdominal syndromes. Pronounced sensitivity to pressure along the abdominal aorta, revealing irritation of the lumboaortic plexus is always present.

Professor Meldolesi discussed pulmonary infiltrations whose tuberculous causation could not be demonstrated. He outlined the occurrence of a group of pulmonary lesions which the phthisiologist should know in order to avoid dangerous errors in diagnosis and treatment. So-called fugacious infiltrations must be differentiated from phthisiogenetic infiltrations, three types of which were considered by the speaker. He also discussed permanent infiltration of the type of Besnier-Boeck-Schaumann's disease: with epithelioid cells and giant cells. The etiologic basis for this form is completely obscure; some authors suggest a concept of attenuated tuberculosis and others a leprous origin.

Professor Fici discussed pulmonary tonus and pulmonary neurodystonia as related to an extensive or circumscribed excitability of the vegetative nervous system. Sometimes neurodystonia may be segmental, involving a minimal area. He analyzed the pathogenesis of the different localization of the bronchial murmur in exudative pleurisy, of atelectasis (massive, acute transitory lobar, partial), and of the variations of the volume of the lungs. Of the vascular neurodystonias, Professor Fici referred particularly to hemoptysis. Vasomotor disturbances of the vegetative innervation may be influenced by the action of hormones, meteorologic variations or a concomitant hysteric syndrome. In fulminant hemoptysis the possibility of efficient action of histamine was considered. Mixed myogenetic and vascular neurodystonia may be indistinguishable. Pathogenic mechanisms of some fugacious pulmonary infiltrations may be tied to the changes of the neurovegetative tonus.

Professor Sagona reported on the national, regional, provincial and communal organization campaign against tuberculosis in Italy. Professor Paola discussed the modern points of view concerning surgical collapse therapy insisting that the favorable result of surgical treatment depends directly on the clinical and immunobiologic condition of the patient who is to be operated on and that pulmonary elasticity should be the essential criterion in selection of the type of treatment. Early forms were considered most benefited by immobilization of the lung.

Benign spontaneous pneumothorax as secondary or symptomatic and primary idiopathic groups were discussed by Dr. Fichera.

BERLIN

(From Our Regular Correspondent)

Feb. 26, 1948.

Organization of Scientific Medical Societies

The organization of German scientific medical societies in the Soviet zone has been approved by Order 124 of May 21, 1947, by Marshall Sokolowski. Such societies of specialists (surgeons, gynecologists, internists, etc.) may be organized under the direction of the minister-presidents of the *laender* and provinces in the university cities of Jena, Leipzig, Rostock, Halle and Greifswald and in cities which, including the suburbs, have more than twenty-five specialists in the particular field. The activities of these societies are controlled by the Central Administration of Health and its suborganizations. Each society has to register with the Central Health Organization of the province or land in which the society has its principal place of business. The order also authorizes the president of the German Administration of Health in the Soviet zone of occupation to organize a scientific medical society of specialists at the medical faculty of the University of Berlin and to call conferences and meetings of specialists in the zone. The agenda of such conferences and meetings has to be submitted for approval to the head of the department of the Central Administration of Health, which has jurisdiction over the matter, at least two months ahead of time.

Attached to the order is the text of the by-laws for establishment of these societies, obligatory on all societies which are organized pursuant to the order. In article 1 of the obligatory charter, the purposes of these societies are defined as follows: the promotion of exchange of research in scientific and practical medicine; the promotion of specialized knowledge; the democratization of the German medical science and of the whole scope of medicine and the uncovering of fascist ideologies within the field of medicine and their complete extermination.

Rehabilitation of the Physically Impaired

On Sept. 10, 1947 a meeting of the Zonal Council of Committees for the Rehabilitation of the Physically Impaired took place in Goslar (British zone). These committees consist of representatives of public health and public welfare, specialists in orthopedics and qualified orthopedic mechanics. All problems of aid to the physically impaired, particularly to war veterans, were discussed. Through the zonal council, the securing of materials to make artificial limbs, the necessary business transactions and the distribution of the materials to orthopedic shops and plants will be coordinated in order to make the amputees independent within the shortest possible time. The committees will also arrange for and supervise professional reeducation. Two rehabilitation schools, in Pyrmont and in Malente, are already in operation. More are to follow.

Miscellany

SOCIAL HYGIENE IN THE FORT KNOX EXPERIMENT

More than a year ago the Army established at Fort Knox, Kentucky, a pilot model of universal military training. As Major Gen. John M. Devine has pointed out, the Army realized that the training of young men involves much more than eight hours a day in technical military training; it must assume responsibility for behavior standards and moral welfare. The experimental unit at Fort Knox has been in operation more than a year and about 1,300 young men have completed training. Only 5 cases of venereal disease, 2 of them in married men who contracted the infection from their wives, have developed; yet there is no prophylaxis station in the unit and no issue of prophylactic kits.

Two periods in the training program are devoted to sex hygiene, each being a cooperative effort by the physician and the chaplain. The physician, who speaks to the trainees first, reveals the normal functions of the human body, treats sex in a matter of fact mnnner and discusses the symptoms and after-effects of venereal disease. His instruction emphasizes continence as the only sure preventive of venereal disease.

The chaplain takes up the instruction, discussing the moral law, the dignity of women and their function in the reproduction of the race. His discussion also is matter of fact, open, honest, intelligent and frank. These two periods constitute the whole course in sex hygiene; however, the chaplain is available for consultation with individuals at any time and further group instruction is given if he thinks it is desirable.

Sex instruction comprises only a minor part of the social hygiene program. Adequate athletic facilities exist, and six hours a week are devoted to physical training, two to body building and the other hours to instruction on how to play games. Half of this group of typical American boys did not know the basic rules of any team sport, and 10 per cent of them had never played any team game of any kind. The competitive games are carried at the lowest practical level. Competitive athletics which take place every Saturday afternoon have been surprisingly successful in keeping boys in camp over the weekend. Citizens of Louisville and Elizabethtown have invited trainees to their homes and have done a magnificent job in providing and chaperoning young ladies for dances. After four weeks of training in camp, trainees may, under certain conditions, go to town, but they must stay at the Service Club or at an approved home. Although Louisville is " wet" it is an offense in Kentucky, as in most states, to sell liquor to minors and all trainees wear an identifying patch which shows that they are under 21 years of age. Letters were written to every bartender in the city asking them not to sell liquor to any one who wears this patch because that person is a minor. The bartenders have cooperated in this respect.

The most important step in the social hygiene program is the general attempt to raise the moral tone of the organization, to establish standards of behavior and manners that will be a credit to the unit, to encourage the decent against the indecent and the good against the bad. In summary of the program the general said that all this is based on the warm belief that the average American boy of 18 is essentially sound, that he is instinctively decent and that he will do the right thing if he knows what it is.

Medical Motion Pictures

FILM REVIEW

Occupational Health Problems. 16 mm., color, sound, 1,500 feet (one reel), showing time thirty-eight minutes. Prepared in 1947 in cooperation with the American Association of Industrial Physicians and surgeons, Brooklyn Industrial Health Committee, Industrial Health Service of Brooklyn Tuberculosis and Health Association, and others through a grant for instruction by the DeVilbiss Company. Producedbyandprocurable from the Medical Film Guild, 167 West Fifty-Seventh Street, New York 19.

As the film opens, the narrator begins to talk while the observer is trying to read titles. One is impressed that, due to the lack of proper health supervision, over 400,000 man days are lost each year in industry and one-fifth are preventable. The following subjects are included: (1) the penny plan for health education in industry; (2) the technic of preemployment examination; (3) technic of tuberculosis surveys; (4) aerosol therapy and asthma; (5) nutrition in industry; (6) treatment of the common cold; (7) absenteeism in industry; (8) treatment of burns, and (9) industrial hygiene problems. This last phase of the film was produced under the direction of the Department of Industrial Hygiene, State of Illinois., using typical problems created by Chicago's industrial plants. (10) Comparative costs of an industrial hygiene department versus that resulting from compensation. This demonstrates some of the advantages of an industrial health program.

In one scene the right hand of a patient is shown; however, the narrator states "this left hand was caught in a machine." The film has a number of good points. Its general conception of the scope and nature of occupational health is sound, although more dramatic presentation might have been used. Much of the early footage is given over to charts and similar details; however, there is not sufficient time to digest this material. The photography is excellent, particulary those sections on treatment of burns and of asthma which, although they reflect the sponsor's interest, are not distinctively occupational health problems. The film is not regarded as up to professional levels. It might be quite useful as a general introduction to those who are not familiar with the subject.

Abdominal Tube Pedicle Graft to Lower Extremity via Wrist. 16 mm., color, silent, 500 feet (one reel), showing time twenty minutes. Prepared in 1947 by, and procurable on loan from, George A. Friedman, M.D., 111 East Sixthy-First Street, New York 21.

The purpose of this motion picture is to clarify a grafting operation. It illustrates the formation, migration and inlay of the abdominal tube pedicle. The film utilizes motion and still inserts to record the shifting of tubed pedicle flaps from the body to the arm and then to the lower extremity. The contents of this picture comprise a composite of many cases, emphasis being placed on procedure rather than on a single case. In one patient a lesion which is somewhat difficult to make out is shown and one or two immediate final stages are illustrated. Generally speaking, the photography is poor. Several colored still photographs have been copied and interspersed throughout the film. The titles are clear. This production could be shown to audiences unversed in plastic surgery to illustrate one of the more tedious processes required.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

Serum Iron Levels in Adolescent Girls: Study of 3 Cases. Frances A. Johnston.—p. 716.

Tongue Lesions and Niacin Deficiency.—From 1942 to 1945 60 children with lesions of the tongue were observed at Bellevue Hospital by Bakwin and his associates. Four types of lesions were observed: acute glossitis; glossitis migrans, or geographic tongue; mild swelling of the tongue, and fissures of the tongue. Effect of large doses of niacinamide (nicotinamide U.S.P.) (8 to 20 mg. per kilogram of body weight) were studied, and results were compared with those for an untreated group. Acute glossitides improved spontaneously or after chemotherapy. Of the patients with swollen and fissured tongues who were treated with niacin (nicotinic acid U.S.P.) a larger proportion showed improvement (14 of 17) than was observed among patients who received no therapy (4 of 16). In no patient was complete cure effected, although treatment was continued in 2 patients for twenty-six months. Glossitis migrans was unaffected by nicotinamide therapy. Diets of children with changes of the tongue were not demonstrably different from the diets of children without such changes. Results support the view that nicotinic acid has a favorable influence on the nutrition of the tongue. They fail to substantiate the view that the lesions of the tongue commonly seen in children are due to nicotinic acid deficiency.

Penicillin in Gonococcic Vaginitis.—Clarke and Eisenberg treated 20 Negro girls from 2 to 10 years of age, who had uncomplicated, previously untreated gonococcic vaginitis, at the Chicago Municipal Social Hygiene Clinic. Purulent or mucopurulent vulvovaginal exudate was present in each patient with local inflammatory signs of varying degree. At least one smear of the vaginal secretion showed typical gram-negative intracellular diplococci *before* treatment. Children were treated with a single intramuscular injection of 100,000 or 200,000 units of penicillin in beeswax and peanut oil, with prompt clinical and bacteriologic remission in each case. An apparent recurrence after one hundred and twenty-two days, cured by retreatment, was considered to be a reinfection. Untoward reactions to treatment were not observed.

Detection of Preinvasive Carcinoma by Smears.—According to Pund and his associates incipient cancer of the cervix uteri is usually noninvasive. Adequate therapy in this phase should result in cure in 100 per cent of the cases. The endocervical smear stained according to the method of Papanicolaou offers the best routine method of detecting neoplastic cells of the cervix in their preinvasive phase. The diagnosis must be confirmed by biopsy or endocervical curettage. A study of routine endocervical smears has enabled the authors to detect 7 cases. Biopsy of two or more sites should be carried out, exercising care to choose the proper sites—the endocervical junction at the external os.

Fibrosis Uteri.—Shoemaker and Kahler point out that the criteria for the diagnosis of fibrosis uteri have never been clearly defined and its existence as a separate entity has been denied by some. The surgeon who has made a preoperative diagnosis of uterine myoma or adenomyosis may encounter at operation a symmetric, slightly enlarged uterus. This type of uterus gives rise to menorrhagia. In order to determine whether the disease is a clinical entity, fresh uteri received from the surgery division were inspected, measured and opened along the middle of the anterior surface. The organ was then halved by continuing the incision, and a block of tissue was removed to represent the full width of the uterus. Twenty-seven uteri with fibrosis and 28 control uteri were studied. The control group consisted of necropsy and surgical specimens which were normal or contained leiomyomas, adenomyosis or endometrial polyps. The 27 cases of fibrosis uteri were found among a total of 245 uteri. The patient with fibrosis uteri has a history of profuse menorrhagia without metrorrhagia and usually without dysmenorrhea. On pelvic examination the uterus is symmetrically enlarged. The excised uterus is a slightly to moderately enlarged organ. The myometrium is pale, finely textured and thickened, with increased consistency. On microscopic examination an increase of fibrous tissue is observed in the submucous layer of the myometrium, appearing as an increase of both the interfascicular and the intrafascicular connective tissue. This study does not reveal the exact causation or pathogenesis of the lesion but does provide evidence that it is not an end stage of chronic metritis, that hypertrophy of muscle fibers plays a minor role and that it is not a form of subinvolution of the uterus. The authors conclude that fibrosis uteri may be considered a fairly well delimited clinical and pathologic entity. The lesion consists of fibrosis of the myometrium.

Tracing Device for Surface Lesions. L. B. Newman.—p. 42.

Evaluation of Disability.—Hellebrandt and associates state that the upper extremities are used in nearly all occupational pursuits. Deformities, injury or disease affecting the power of the muscles reduce man's ability to work. When this occurs grave economic problems related to the adjudication of compensation claims arise. A series of self-contained, ink-writing ergographs have been developed for the appraisal of the functional capacity of the major articulations of the upper extremity. Preliminary trial with these instruments suggests that work tolerance may be estimated with greater accuracy ergographically than by judgment of the examining physician and that ergography may be clinically useful in disability evaluation, because it provides a simple quantitative tool by virtue of which the following measurements may be made: (1) initial functional capacity; (2) progress under treatment; (3) the end point of effective rehabilitation, and (4) the degree of residual disability.

Cancer of Stomach. J. D. Hayes.—p. 181.
*Tularemia in Arkansas. R. H. Rigdon and C. R. Chesnutt Jr.—p. 183.

Tularemia in Arkansas.—Rigdon and Chesnutt review 26 cases of tularemia at the University Hospital in Little Rock from 1940 to 1946. There were 18 cases of the ulceroglandular type, 3 of the pneumonic form and 2 each of the oculoglandular and typhoid types; 1 case was unclassified. Cases are presented to illustrate each of the four types of infection. In most of the cases treatment was with sulfonamide drugs. Now streptomycin is the drug of choice in the treatment of tularemia.

*Treatment of Miliary Tuberculsois with Promizole. Edith M. Lincoln, S. Stone and Olga R. Hoffman.—p. 56.

Rh Protective Factor.—Bloxsom and Matthaei reported in an earlier article an infant with erythroblastosis fetalis who accidentally received a massive transfusion of Rh-negative blood. Since the course of the hemolytic disease of this infant was favorably altered by the large transfusion, the possibility was suggested that an Rh-negative donor's serum might possess some factor that suppressed or inhibited the Rh antigen-antibody reaction. If this is true, the serum of Rh-negative donors should be of as much value in transfusions into infants with erythroblastosis fetalis as the Rh-negative red blood cells. The present study was undertaken to determine whether this factor could be demonstrated in Rh-negative blood serums. The serums of the Rh-negative bloods employed in these studies have been shown to contain an anti-Rh antigen-antibody reaction factor that inhibits the Rh antigen-antibody reaction. The serums of the Rh-positive bloods have been shown to contain no anti-Rh antigen-antibody reaction factor except for the small amount found in one man who is heterozygous. This anti-Rh antigen-antibody reaction factor is a specific inhibiting substance for the Rh reaction. The natural occurrence of this anti-Rh antigen-antibody reaction factor serves as a vital protective means for Rh-negative persons and for infants subject to hemolytic disease of the newborn. It is believed that the serum of Rh-negative blood is probably even more valuable than its cells for the transfusion of infants with erythroblastosis fetalis due to anti-Rh agglutinins. The males tested showed in their blood serums greater amounts of this anti-Rh antigen-antibody reaction factor. It is possible that blood from such donors will be more effective in the treatment of hemolytic disease of the newborn. It is hoped that the use of suitable Rh-negative blood and blood serums at regular intervals before delivery may result in the salvage of a larger number of those infants. The presence of the anti-Rh antigen-antibody reaction factor in the serums of Rh-positive males may point to the fact that those males are heterozygous.

"Promizole" in Miliary Tuberculosis.—Lincoln and his associates tried "promizole" (4,2'-diaminophenyl-5'-thiazolylsulfone) first in that form of tuberculosis which has the worst prognosis. They treated 5 successive patients with meningitis without beneficial effects. Acute generalized hematogenous tuberculosis was then selected for treatment with the drug because the course of this disease is more prolonged than that of meningitis, thus allowing more time for action of a drug. The authors have employed "promizole" in 11 children with acute miliary tuberculosis. All showed evidence of primary pulmonary tuberculosis as well as mottling of miliary or slightly larger size throughout both pulmonary fields. Three of these patients have been treated for less than six months, and although all are doing well it is too early to evaluate results of therapy. Three patients were treated for less than a month. Five consecutive patients with acute generalized miliary tuberculosis were apparently adequately treated with "promizole." Of these, 2 children died forty-three days and four and one half months, respectively, after therapy was begun. Three children showed complete recession of roentgenologic evidence of miliary tuberculosis and are alive thirty to thirty-three months after the drug was first given. In these patients who survived acute miliary tuberculosis the primary pulmonary lesions cleared slowly and in 2 cases went on to cavitation. In 1 case roentgen evidence of the primary focus is still present. One child developed tuberculosis of the spine, choroiditis and positive urine cultures for tubercle bacilli while taking the drug. All 3 patients are still receiving maintenance doses of "promizole." The drug is goitrogenic and has a stimulating effect on secondary sexual characteristics, causing enlargement of nipples and mammary tissue and growth of pubic hair. Toxic effects which would require permanent discontinuance of the drug were not observed.

Cancer of Lip. I. MacDonald.—p. 37.

Radiation in Cancer of the Breast.—According to Goin, clinical stage 1 cancer of breast means that the tumor seems to be limited to a lobule of mammary tissue, that the skin is uninvolved and that no axillary or supraclavicular nodes are palpable. Pathologic stage 1 means that no carcinomatous cells could be found in the tissue removed. Clinical stage 2 carcinoma means that the skin is involved or that palpable nodes are present, or both. Pathologic stage 2 means that the skin was infiltrated or that metastases to glands were demonstrated, or both. Stage 3 cancer of the breast indicates the presence of distant metastases. The author thinks that stage 1 mammary carcinoma should not be irradiated but should be treated by radical mastectomy. Stage 3 carcinoma of the breast should be treated entirely with irradiation. Stage 2 cancer of the breast should be treated by radical mastectomy plus postoperative irradiation. There is little to lose and perhaps much to gain by the castration of menstruating women who have cancer of the breast.

Leukonychia.—Montgomery points out that white spots on the nails are especially frequent in young women and are observed more frequently on the fingers than on the toes. Injury, particularly that incident to manicuring, may play a part in the development of some of the white spots and streaks. They may occur as the result of severe fever. White stripes or cross ridges have been observed corresponding to severe attacks of typhoid or typhus or other fevers, and 1 case has been reported in which each attack of relapsing fever was followed by a leukonychia stripe. Nerve lesions may cause white stripes on the nails; they are frequent in the neurotic person; they concur with constipation, indigestion and acne, and they may have some connection with the menstrual period. Poisons such as arsenic or alcohol may play a part in the development of white spots and stripes in the nails. Often leukonychia *indicates a more or less grave, persistent state* of ill health.

Nutritional Studies on Milk Fat: III. Effect of Treatment of Milk Fat with Certain Solvents on Growth of Young Rats. E. L. Jack and E. B. Hinshaw.—p. 715.

Caloric Restriction and Skeletal Growth.—Handler and his co-workers found that the rate of skeletal growth in young rats was roughly proportional to the rate of general body growth when caloric restriction was the factor limiting growth. Restriction of caloric intake to about one half of that of control animals fed ad libitum resulted in a complete cessation of both skeletal and generalized body growth. Histologically the bones of such animals were identical with those usually found in "partial inanition." In larger, not quite completely grown rats, caloric restriction sufficient to cause a loss of 40 per cent of their initial body weight only slightly decreased the rate of skeletal growth. The plasma concentration of calcium was normal in all animals, while that of inorganic phosphate was below normal in the young caloric-restricted animals but not in the older rats.

Effect of Added Thiamine in Twins.—Robertson and his associates found that administration of 2 mg. daily of thiamine for four and one-half months to half of thirty-six pairs of identical twins resulted in improvement in weight and height gains and in manual dexterity and prolonged memory test scores that were of questionable statistical significance. The tests used for measuring vision, intelligence, reasoning, arithmetic, rote memory and code substitution gave results without statistical significance. Twenty-five pairs of the twins were kept in the study for four and one-half months longer. When they were again tested at the end of this period, that is, after nine months of therapy, no gains of statistical significance were evident in any of the tests.

Papanicolaou Stains for Gastric Contents.—Campbell and Grimm studied the cell structure of gastric contents by means of the Papanicolaou method of preparing and staining slides. Gastric contents of 200 patients were examined: 28 had gastric, duodenal or gastrojejunal ulcers; 2 had pernicious anemia; 1 had gastric polyps; 1 had carcinoma of the pancreas; 5 had disease of the biliary tract; 7 had carcinoma of the stomach, while the balance were controls or patients with disease of the lower part of the gastrointestinal tract. The authors realize that the possibilities of this method for detecting or at least suspecting early gastric carcinoma cannot be completely determined without the lapse of more time to follow up the patients covered in this study. A subsequent comparison of slides of their gastric contents with those now on hand, especially in those that later have cancer of the stomach, will be necessary. The Papanicolaou stained smear offers promise of confirming a diagnosis of cancer of the stomach in cases in which the lesion has advanced to the point where it can be diagnosed by roentgen ray. Of 5 cases of carcinoma of the stomach in which the authors were able to obtain the surgical or autopsy specimen, they were able to demonstrate cancer cells in 4. Cancer cells were found in 1 of 2 patients in whom the diagnosis had been established clinically; the other case was one of linitis plastica, in which a study of the gastric contents may never be productive. The Papanicolaou stained smear of gastric contents is a relatively simple procedure. It is inexpensive to conduct. It is adaptable to studying large numbers of patients with a minimum of inconvenience and expense.

Contribution to Etiology, Diagnosis and Therapy of Pemphigus. D. I. Macht and M. Ostro.—p. 651.

Etiology, Diagnosis and Therapy of Pemphigus.—According to Macht and Ostro, the blood serum of patients with true pemphigus exhibits a specific phytotoxicity on the root growth of Lupinus albus seedlings, which is not exhibited by the serums of most other dermatoses (Pels-Macht or Macht-Pels test). This toxic reaction of the serum of patients with pemphigus is diminished or completely destroyed by exposure to specially filtered roentgen rays, while serums from patients with other dermatoses are not affected by such rays (Macht-Ostro reaction). The two tests performed simultaneously lead to a reliable differential diagnosis of pemphigus. As suggested by these observations, deep roentgen irradiation was performed on 10 patients, 6 men and 3 women between the ages of 45 and 68 and 1 young woman with pemphigus. The rays were filtered through 1 mm. aluminum and 2 mm. copper. The dosage varied from 43 r to 86 r measured in air. A rest period of two or three days was usually given between each treatment and seldom were more than three treatments made in close succession. Detoxification of the blood serums of all patients resulted as determined by the phytopharmacologic test. This was accompanied by definite clinical improvement and remission in 7 of the patients with a permanent remission or cure in 2. The young women with fulminating pemphigus vulgaris and 1 middle-aged man with pemphigus foliaceus did not improve clinically and died. A third patient with extensive pemphigus vulgaris showed some slight clinical improvement but is now rapidly approaching the end. The last 2 patients were treated with rays filtered not through 2 mm. copper but through 0.5 mm. copper. Further investigation of the clinical *therapeutic possibilities* of radiotherapy for pemphigus as checked or controlled by phytopharmacologic tests is suggested.

*Some Results in Treatment of Lupus Vulgaris by Calciferol. T. E. Anderson.—p. 562.
Prognosis in Pulmonary Tuberculosis. R. Fraser.—p. 566.

Evaluation of Operations for Hypertension.—Mitchell says that although the cause of hypertension is uncertain, the main surgical attack has been directed against peripheral sympathetic structures. To cover various etiologic possibilities a blunderbuss technic has been evolved requiring extensive autonomic ablations. Different surgeons have differing ideas about what they wish to achieve, and these varying views are reflected in their operations. Nearly all wish to produce vasodilatation in the abdominal splanchnic area, and in addition most believe that a degree of somatic vasodilatation is desirable. The author reviews various types of operations and suggests that certain of the failures may be explained on anatomic grounds. It is shown that the Peet, Allen-Adson and Smithwick procedures may not interrupt all the sympathetic fibers to the abdominal splanchnic area or to the kidneys and adrenals. Aortic and esophageal filaments arising from the sympathetic trunks or splanchnic nerves above the levels of section, paraaortic nerves (when present) and sympathetic fibers in the phrenic nerves, esophageal plexuses or vagal trunks may all reach the abdomen and may escape interruption in these sympathectomies. Section at the level of the second lumbar ganglion may miss renal contributions arising from the sympathetic trunks below that level and may not interrupt communicating fibers between the renal plexus and the superior spermatic, gastroduodenal or intermesenteric nerves. It is suggested that the optimum sympathectomy for hypertension is bilateral resection of the sympathetic trunks from the fourth thoracic ganglion to the third lumbar ganglion and removal of the splanchnic nerves.

Calciferol in Lupus Vulgaris.—Anderson says that in the past year 71 cases of lupus vulgaris (19 males and 52 females) have been treated with calciferol (vitamin D_2) at the Aberdeen Royal Infirmary. Eighteen of the patients are either still undergoing treatment or have defaulted. One patient died. In this patient calciferol treatment had been interrupted on account of toxic symptoms. A course of treatment has been completed in 52 of the patients. Of these, 41 were apparently cured and 8 were greatly improved but doubtful; the remaining 3 were apparently cured at the end of a six months' course of treatment but are relapsing and require further treatment. Calciferol was the exclusive treatment in 39 of the 52 patients; in the other 13 some adjuvant treatment was used, such as intradermal chaulmoogra oil esters, carbon dioxide snow or the Kromayer lamp. The duration of calciferol treatment varied from two and one half to eight months (average 6.1 months). The usual dosage of calciferol was 50,000 international units three times daily by mouth in cases in which this dosage was tolerated. In most cases this has been reduced to 100,000 units a day after three months; but in some instances 150,000 units have been administered daily for a full six months. A rise of the serum phosphate level seems to be a more reliable index to early intoxication than the calcium level. Toxic symptoms appeared in 32 of the patients, but subsided. The results obtained with calciferol are superior to those formerly obtained by other methods.

Special Intermediary Type Between Thomsen's Disease and Myopathia: Contribution to Study of True Muscular Hypertrophy in Progressive Muscular Dystrophia. L. Rouquès, P. Guilly, J. Pautrat and J. Lapresle.—p. 481.
*Vegetative Hypertrophic and Atrophic Sciatic Neuralgia. V. Pitha.—p. 491.

Vegetative Sciatic Neuralgia.—Pitha reports 15 cases of vegetative hypertrophic and atrophic sciatic neuralgia, a syndrome associated with hernia of the intervertebral disk and classic funicular sciatica and with certain cases of the Guillain-Barré syndrome and neuritis. This vegetative sciatic neuralgia of rheumatic origin is to be considered a new clinical entity different from that of classic sciatica (Cotugno's disease). This atrophic and hypertrophic sciatica is characterized by a certain type of pain. Except for the initial dramatic attack of pain, it is relatively mild, always tolerable, sometimes burning and occasionally diffuse, particularly in the area of the calf. The muscle group involved is severely and diffusely painful on palpation, in contrast to a mild or absent Lasègue's sign. In the initial acute stage of the disease there may be present occasionally the classic signs of sciatic radiculitis, and the term "total neuralgic phase of vegetative sciatica" is suggested for it; the hypertrophic type may often be associated with intense pain in the lumbar region and in the abdomen. The muscular changes occur slowly after the acute stage, and they characterize the chronic stage. There are no real disturbances of motility, and muscular weakness may occur only after a prolonged walk. The muscular changes are diffuse and involve the entire limb. The upper half of the calf is particularly affected, and hypertrophy of the thigh may be associated with atrophy of the leg in the same patient. There are no fibrillary tremors. The muscle tonus is increased in the hypertrophic form and diminished in the atrophic form. The idiomuscular excitability is mildly and regularly diminished in the hypertrophic and in the atrophic sciatica. In general there are no changes in the tendon reflexes in both forms. The course of the atrophy is a slow one, sometimes of several years' duration, but the hypertrophic form develops in several months. These muscular symptoms are to be considered as the most important clinical aspect of the direct vegetative innervation of muscles. It may be safer to explain the common sciatic changes on the basis of a vegetative pathogenesis of the muscular changes than on one of inactivity.

Determination of QT Interval in Electrocardiogram. W. Wolf.—p. 533.
*Problem of Decapsulation of Kidneys in Acute Anuresis. W. Pilgerstorfer.—p. 535.

Decapsulation of Kidneys in Anuresis.—Pilgerstorfer treated 1 man aged 23, who had acute nephritis associated with anuresis, by unilateral removal of the renal capsule. Previous conservative treatment consisting of two days of fast and then a diet of dried, uncooked fruits. Intravenous injections of strophanthin and dextrose and short wave radiation had proved ineffective in promoting the secretion of urine. Considerable amounts of urine were passed within a few hours after the surgical intervention. In seven postoperative days the secretion of urine amounted to about 34 liters, 14 of which were excreted in the first thirty-six hours. Simultaneously the residual nitrogen, which before the operation had been increased to 197.4 mg. per hundred cubic centimeters, was restored to normal as were the blood pressure, the specific gravity of the urine and the function of the kidneys. The lightning, lifesaving result of the unilateral decapsulation in this case suggests that the operation should be performed in cases of acute nephritis in which, in the absence of severe histologic changes in the glomeruli, anuresis may result from the mechanical compression of the highly edematous kidney by the tight capsule. The liberation of the kidney from the compressing capsule may be compared to the flood of water which has been dammed up in a reservoir and which pours out after the removal of the obstruction. Due to the diuresis resulting in the decapsulated kidney the swelling in the other kidney also subsides and both kidneys resume their function. In contrast to this, diuresis will not take place even from bilateral decapsulation in cases of severe subacute glomerulonephritis associated with extensive extracapillary proliferation.

Book Notices

Viruses. By Max A. Lauffer, Ph.D., Associate Research Professor of Physics, the University of Pittsburgh, Pittsburgh. From the Twentieth Annual Priestly Lectures. Sponsored by Phi Lambda Upsilon Honorary Chemical Society. Paper. Pp. 62, with 42 illustrations. Pennsylvania State College, State College, Pennsylvania, 1946.

This volume contains five chapters which served as the twentieth annual Priestly lectures. The subjects chosen by the author, who is an associate research professor of physics of the University of Pittsburgh, are largely concerned with biophysical properties of certain viruses which have become available in large enough quantities and in states reasonably pure enough to warrant biophysical analyses.

The first lecture deals with "viruses as molecules"; the fourth considers "viruses as organisms." This in itself does not imply a contradiction, since it becomes more and more obvious that a variety of agents are included at present under the heading of viruses. The second and third lectures are entitled "the size and shape of viruses" and "the disintegration of viruses," whereas the last considers "viruses and human welfare."

The experimental data quoted, of which a sizable share involves the author's work, are concerned to a large extent with plant viruses, tobacco mosaic virus in particular, and the influenza viruses. The biophysical apparatus used in the study of the various properties of the agents is briefly described in the corresponding sections, and the theories and limitations of the technics are adequately discussed. Thus it is possible for those less well versed in biophysical technics to follow the line of thought without difficulty, which renders this volume valuable to those interested in the virus field in general.

The last lecture sums up some of the better known facts about the profound influences exerted by virus infections of plants, animals and man on the course of history and man's efforts to overcome these scourges. Some of them have been practically eradicated; other attempts led to encouraging results. Some of these have been overrated by the author, and to link biophysical studies with the conquest of certain virus diseases seems somewhat forced. To quote: "Yet who ever could have dreamed that the crystallization of urease and of pepsin would open the way for the conquest of influenza?"

Practical Obstetrics. By Bruce T. Mayes, M.V.O., M.B., B.S., Professor of Obstetrics, University of Sydney, Sydney. Cloth. Price, 57s. 6d. Pp. 306, with drawings by Vergil Lo Schiavo, B.A. The Australasian Publishing Co., Pty. Ltd., Bradbury House, 55 York St., Sydney, N. S. W.; 182 High Holborn, London, W. C. 1, 1947.

It was the author's intention not to write a textbook but to present a number of practical clinical discussions in a form that will preserve the atmosphere of a doctor's office, an operating room or the bedside rather than that of the lecture hall. In this the author has succeeded admirably, for his style of presentation is delightfully informal and most unusual in a book dealing with medicine. Of the twenty-two chapters in the book, eighteen are devoted to obstetrics, two to sterility, one to artificial insemination and the last one to "Queries and Views."

The first chapter deals with postpartum hemorrhage, and this is proper because hemorrhage is the most important cause of maternal mortality. Throughout the book the author demonstrates his vast experience in obstetrics. He is ultra-conservative, yet he has not failed to accept all that is progressive in obstetrics. He illustrates and describes the use of episiotomy, direct local anesthesia and the low cervical cesarean section. He also takes up the matters of the Rh factor and rubella and their significance in obstetrics.

There are a few recommendations with which many will disagree. These are the Credé expression for the separation of the placenta, intrauterine douches for the control of postpartum hemorrhage and chloroform to relax spasms of an eclamptic convulsion.

The book not only is written in an interesting fashion but is beautifully illustrated by drawings and photographs, many of which are in color. Throughout the book are case reports which greatly enhance its teaching value. This is a real textbook, not only for medical students and general practitioners, for whom it is intended, but also for specialists in obstetrics.

Successful Dental Practice: Patient Relations—Patient Education—Treatment Planning—Business Principles. By J. Lewis Blass, Ph.G., D.D.S., Associate Professor of Periodontia, New York University College of Dentistry, New York, and Irvin Tulkin, D.D.S., Post-Graduate Instructor on Dental Practice Management, First District Dental Society of New York. Twenty drawings by Jean McConnell. Fabrikoid. Price, $6. Pp. 221, with 42 illustrations. J. B. Lippincott Co., 227-231 S. 6th St., Philadelphia 5, 1917.

Untiring effort and much time have gone into the preparation of this book. The authors have presented cogent and well thought out principles and procedures which can be of great assistance to the reader. Although this book is intended particularly for practitioners of dentistry, much of its matter will apply to the practice of medicine. In both professions technical ability is recognized as the foremost reason for success, but a host of other factors influence each particular practice. The solutions to various problems which this book offers are based on the experience of successful practitioners.

The book is divided into five parts. Part 1, "patient relations," presents attitudes and procedures helpful in securing effective relations with patients. Receiving the patient, educating the patient during the examination, planning and presenting the diagnosis, outline of treatment, fees and terms are discussed in detail. Particularly interesting and instructive is the portrayal of conversational technics for meeting the problems of the patient in the initial interview. These problems pertain principally to fees, fear of pain, prejudices and misconceptions or ignorance. The vast importance of creating and maintaining the confidence of the patient is emphasized throughout the chapter.

"Office Management" is the title of Part 2. The authors present a comprehensive study of fee arrangements, bank loans, credit and collections, office responsibilities, secretary's duties, records, practice control and correspondence. Emphasis is placed on retaining the patient's good will.

Part 3 covers "Insurance and Legal Considerations and Personal and Psychologic Considerations." This section is the most valuable part of the book. The observations quoted from Charles H. Kendall on the "value of psychology to the dentist both in handling his patients and in knowing himself" and the material furnished by Isabelle Beaumont on the "management of the neurotic patient" are well worth the price of the book.

Part 4 is devoted to "Business Considerations," and the recent graduate will find valuable information about various types of practice as well as adequate listings of practice locations. Problems of practice and practice growth are covered thoroughly, and conclusive answers are given to forty-three questions concerning patient relations.

The book concludes with an "Atlas for Patient Education." The publishers are to be commended for the beautiful and distinct illustrations which assiduously conform to the text.

It is impossible in a brief review to supply an adequate idea of the importance of this book, which is characterized by truth and dignity.

Principles of the Contact Lens. By H. Treissman, M.B., B.S., F.R.C.S., and E. A. Plaice. Cloth. Price, $3.50. Pp. 88, with 40 illustrations. The C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3, 1947.

This small textbook is really a handbook for the guidance of the ophthalmologist in selecting those patients who might wear contact lenses with benefit.

There is an excellent section with clear diagrams on the optics of contact lenses, but the section on indications is neither impartial nor scientific. It is unfortunate that ophthalmologists are rather sharply divided on the question of contact lenses, some being ardent advocates, others being as ardent opponents. The authors clearly belong to the former group, and therefore the indications for use of contact lenses will not be universally accepted.

Sattler's veil, or the fogging of vision which results from corneal edema, is the greatest single problem facing those who work with contact lenses today. The proposed method of solving this problem by simply removing the contact lens and reinserting it a half-hour later is open to severe criticism and entirely unsubstantiated by experience in this country.

On the whole, this handbook is not impartial enough to be a good handbook and is not nearly detailed or explicit enough to be a good source of information on contact lenses.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

INDUCTION OF LABOR

To the Editor:—Is the use of ergot for induction of labor a recognized and safe procedure? The regimen consists of an enema, 12 grains (0.78 Gm.) half strength powdered ergot by mouth and one hour later 6 grains (0.39 Gm.) of powdered ergot, if uterine contractions have not previously ensued. Artificial rupture of the membranes may be performed also if the fetal head is engaged.

K. W. Covey, M.D., Mahnomen, Minnesota.

Answer.—The oxytocic activity in powdered ergot varies greatly. It is far better to use the active principle of ergot, ergonovine, whenever the action of ergot is desired. There have been some reports in the literature describing the use of small doses of ergonovine for the induction of labor. Generally, however, ergot is not desirable for induction because it has a tendency to induce uterine tetany rather than normal rhythmic contractions.

Induction of labor has become a standardized procedure. The patient should be at or near term. The fetal head should be engaged in the pelvis to decrease the hazard of prolapse of the cord. The cervix should be "ripe"; that is, it should be short, its canal having been largely taken up in the process of effacement, and the cervical os should be soft and patulous, easily admitting one or two fingers. If these conditions are fulfilled the simple rupture of the membranes will be followed by the onset of labor after a latent period of one to six hours. No medication is necessary. Obviously, one should have a medical indication for the induction.

"Pitocin" can be used for induction, but it is rarely necessary. One should start with ½ minim (0.31 cc.) given subcutaneously and increase by ½ minim at fifteen minute intervals until a dose of 3 minims (0.18 cc.) has been reached. Total dose should not exceed 1 cc The patient should be watched carefully. If tetany of the uterus develops the drug should be discontinued. Medication should likewise be stopped when regular uterine contractions begin.

REACTIONS TO TESTS FOR UNDULANT FEVER

To the Editor:—Dr. A. J. Durant of the University of Missouri, chairman of the Veterinary Science Department, states that "only 4 per cent of the people that are infected react to the blood test for undulant fever, while 96 per cent of the cattle that have the disease react positively and reliably to the test." *In a survery by the Indiana State Board of Health* of especially exposed groups of persons, 50 per cent of the veterinarians who submitted themselves to the plate agglutination test showed a positive reaction. With fertilizer plant workers the proportion was 27 per cent.

Is the Indiana State Board of Health, or is Dr. Durant of Missouri in error? Should physicians continue to depend on Missouri laboratory procedure, or should it be discarded and should patients be treated on the basis *of their present and past symptoms? The State of Missouri* does not make cultures or use guinea pig inoculations for these tests.

Ira Allison, M.D., Springfield, Mo.

Answer.—The information cited from either source need not be suspected of being incorrect. With reference to the infected human being the important item of the stage of disease at which the tests were performed has been omitted. If serum agglutination tests are performed but once and at random, without respect to the duration of disease, in a large group of persons exposed to brucellosis for some years the proportion of positive agglutination tests may well be 4 to 5 per cent. In the survey of Gould and Huddleson (Gould, S. E., and Huddleson, J. F.: Diagnostic Methods in Undulant Fever (Brucellosis), with Results of Survey in 8,124 Persons, J. A. M. A. **109**:1971-1974 [Dec. 11] 1937), "of 623 infected persons 33, or 5.3 per cent, gave a positive agglutination test." The interpretation of the word "infected" is also at stake. In the passage cited it apparently carries the meaning of having at any previous time been invaded with brucella, without any implication that such invasion ever resulted in disease; and in the reference cited it means by definition a person who exhibited a positive intradermal test reaction and a low to moderate opsonocytophagic titer.

Since brucellosis can seldom be diagnosed with certainty by either clinical or laboratory criteria alone physicians must continue to use all available evidence, epidemiologic, clinical and laboratory, in order to keep the proportion of diagnostic errors to a minimum.

POSTMENOPAUSAL UTERINE BLEEDING

To the Editor:—Is the estrogenic component of various liver extract preparations potent enough to cause endometrial changes? A woman aged 70 began to bleed approximately twenty years after the menopause. She has been taking liver parenterally for several years. Curettage, *carefully done, shows no malignant change. The pathologist reports* "cystic hyperplasia." Pelvic examination reveals essentially normal conditions.

M.D., Philadelphia.

Answer.—There is no appreciable estrogenic activity in liver extracts made for commercial purposes. It is difficult, therefore, to explain why this woman has uterine bleeding at the age of 70 except by placing the blame on the endogenous estrogens elaborated by the adrenal cortex. A number of authors have been able to detect an appreciable amount of estrogen in the body fluids of menopausal or castrate women; likewise, others have been able to obtain an occasional biopsy of the endometrium in menopausal women with cystic hyperplasia. It is conceivable that small amounts of estrogen elaborated for a period of years unopposed by the other elements of the normally secreting ovary such as progesterone might result in a bleeding episode. Nevertheless, the presence of the rare granulosa or theca cell tumors of the ovary must be ruled out in this case.

DETECTION OF PENICILLIN IN TREATMENT

To the Editor:—Please give information regarding the best and most sensitive test now available for detection of penicillin in blood serum.

M.D., Rhode Island.

Answer.—The determination of penicillin in blood serum depends on the serial dilution of serum to which an organism of known, high sensitivity to penicillin is added and compared with dilutions of a standard solution of penicillin prepared in a similar manner. A number of satisfactory methods have been described. The two most widely used are that of C. H. Rammelkamp (A Method for Determining the Concentration of Penicillin in Body Fluids and Exudates, *Proc. Soc. Exper. Biol. & Med.* **51**:95, 1942) employing a beta hemolytic streptococcus as the test bacteria and that of Randall and associates (Randall, W. A.; Price, C. W., and Welch, H.: Estimation of Penicillin in Body Fluids, *Science* **101**:365, 1945) employing Bacillus subtilis.

GOAT'S MILK

To the Editor:—What are the main therapeutic considerations of goat's milk as against cow's milk? Is there any particular demand by internists or pediatricians for fresh goat's milk, and would there be much of a demand if the milk could be obtained canned—not in a condensed state? Is there any canning process available now (except the condensing process) which is *satisfactory as regards keeping qualities,* bacterial count and public health requirements? I am interested in the probable demand if the milk of the goat could be canned, evaporated and distributed.

Bennett W. Muir, M.D., Denver, Colo.

Answer.—Both cow's milk and goat's milk are favorably regarded as human foods because they contribute essential nutrients. Comparative composition tables show some differences chiefly quantitative, in individual components.

A large number of therapeutic claims have been made for goat's milk, but available confirmatory evidence is meager Common practice is the use of goat's milk by persons who cannot tolerate cow's milk because of allergies or other reasons.

There is apparently no great demand for fresh goat's milk as evidenced by the small size of the goat milk industry in this country. Goat's milk is produced in appreciable quantities only in a few limited areas in the United States, one of which is in Colorado. It can be satisfactorily processed in tin either with or without removal of some of the water by evaporation. With the addition of vitamin D evaporated goat's milk is eligible for acceptance by the Council on Foods and Nutrition of the American Medical Association.

BLEEDING PEPTIC ULCER

To the Editor:—What is the information on stopping bleeding peptic ulcers through the use of fibrin or other coagulants taken orally?

M.D., Georgia.

Answer.—The use of coagulants taken orally for bleeding peptic ulcers has not been considered feasible because the agents are either inhibited or destroyed in the stomach. However, Daly reported (Use of Buffer Thrombin in the Treatment of Gastric Hemorrhage, *Arch. Surg.* **55**:208, 1947) that when 30 cc. of seventh-molar phosphate buffer, p_H 7.6, is given in order to neutralize and buffer the gastric contents and followed in five minutes by another 30 cc. of the buffer containing 10,000 units of thrombin, the action of the enzyme is preserved for a sufficient length of time to clot fibrinogen. In his preliminary report he concluded that thrombin given in such a manner is an aid in some cases in the control of gastric hemorrhage. No toxic effects have been observed. The author pointed out that heavy arterial bleeding and bleeding which ordinarily requires a ligature cannot be controlled by this substance alone.

REACTION: TETANUS ANTITOXIN

To the Editor:—Administration of tetanus antitoxin in small doses for passive protection without a preceding skin test is universally condemned but freely practiced. Should a skin test be performed? Is there danger of anaphylactic reaction without it? Could reaction follow the skin test alone? Would administration of diphenhydramine ("benadryl") or a similar drug confer protection?

M.D., Iowa.

Answer.—There is always danger that tetanus antitoxin may cause severe reactions in susceptible persons even if given in small doses for preventive purposes. Preliminary skin tests should be made to determine susceptibility to the antitoxin so that antitoxin can be given safely. Properly made skin tests do not cause general reaction. Whether drugs can be relied on to prevent anaphylactic reaction to tetanus antitoxin is not known.

URINARY INCONTINENCE

To the Editor:—An apparently healthly patient, aged 68, underwent a one stage suprapubic prostatectomy eleven weeks ago. No difficulties were encountered in enucleating the hypertrophied gland, and there was little bleeding. The prostatic bed was filled with four small strips of "oxycel" (absorbable oxidized cellulose), and a size 24 Foley catheter was introduced through the urethra, inflated to 30 cc. and withdrawn into the prostatic bed. Traction was not applied but the catheter was left loose. Ten hours later, as there was no active bleeding, the bulb was deflated and after another fourteen hours the catheter was entirely removed. Convalescence was uneventful. The suprapubic wound healed in ten days. The patient was discharged on the sixteenth postoperative day.

On his first office visit he complained of dribbling in the daytime. During the night he would wake up once or twice feeling the urge to urinate and then without getting out of bed he could void normally at will in the urinal. But as soon as he got up in the morning he would have to wear a pad constantly, and when he was working he kept on dribbling. He is discouraged and I am at a loss to promise much improvement. Is there any hope that he may become fully continent again? Should he keep on wearing a Cunningham clamp or should he wear a rubber urinal? Are there any treatments I could give him:

M.D., New Jersey.

Answer.—A slight degree of incontinence resulting from injury to the external sphincter is observed occasionally following removal of the prostate gland by any of the various surgical procedures employed. In most cases urinary control is recovered gradually in the course of time. The improvement may be slow, however, and eleven weeks after operation is too short a time to lose hope. Patients with postoperative incontinence have been observed in whom natural processes have corrected the condition as long as a year after operation.

If this patient is still incontinent after several additional months, it would be well for him to have a urethroscopic examination to see whether any actual sphincteric damage has occurred. It sometimes happens that a persisting nodule of prostatic tissue has fallen into the sphincteric area, which acts as a wick, preventing proper closure of the sphincter.

Meanwhile a Cunningham clamp is better than a urinal, but the patient should be encouraged to wear it only when absolutely necessary, while at work. While he is at home an athletic support and pads holding the penis up over the symphysis offer a much better method of caring for the incontinence.

Fortunately, permanent incontinence is seldom observed. In such cases surgical procedures to restore sphincteric action have not proved uniformly successful and should be considered only as a last resort. An artificial sphincter, such as that recently suggested by Foley, might be considered at some future date. Optimism and encouragement are the remedies that your patient needs at the present time.

VISUAL TESTS

To the Editor:—What are the equivalent values of visual acuity findings in the two methods of examining eyes wherein one uses 20 for the numerator in the different steps or amounts of visual acuity while the other uses 20 for the denominator? What are the different methods of eye examinations used to make determinations in both of the methods? What is the method of conversion used to obtain the equivalents?

Joseph Bogan, M.D., Arlington, Va.

Answer.—The English system uses feet and inches in recording visual acuity, the Continental uses the metric and the International (1905) uses the decimal system.

The record in one system is generally, though not invariably, transcribable into either of the other systems. In all three systems what is really the numerator of a fraction represents the relative distances from which the test object is viewed by the patient and the denominator represents the distance at which the normal eye should see this same test object. Thus 20/200 in the English system means that the patient is 20 feet away from a test object which he should see at 200 feet; in the Continental (metric) system this is 6/60, i. e. the patient is 6 meters from an object which he should see at 60 meters, and in the decimal system this is recorded as 0.1. Similarly 20/40 = 6/12 = 0.5, and 20/20 = 6/6 = 10 in the respective systems.

URINARY BALANTIDIASIS

To the Editor:—We have found Balantidium coli in the urine specimens of 3 patients. Two of these patients had diffuse aches and pains, weakness, anorexia and loss of weight. They had had a mild febrile reaction. We have been unable to establish the pathogenicity of this parasite. Please send information, and give an opinion as to the pathogenicity of this organism? I might add that Dr. G. A. Slusser found some in a specimen of urine obtained during a ureteral catherization.

S. M. Ramer, M.D., Silver City, N. Mex.

Answer.—The normal habitat of Balantidium coli is the pig, monkey and man. Man becomes infested by ingestion of cysts of the organism. Though the organism conceivably may be transferred directly from man to man, some 25 per cent of cases of balantidiasis can be traced to direct contact with pigs. Since the disease is rare, although exposure in stockmen and in the abbatoir is high, it follows that in general the pathogenicity of this ciliate is of a low order. Experimental transference of the disease from pig or monkey to man has been unsuccessful.

After excystation in the small bowel, the highly motile trophozoites invade the submucosa of the large bowel, producing ulcerations resembling those of Endameba histolytica. Small mucoid abscesses containing the parasites are formed, surrounded by round cell infiltration.

Symptoms usually are those of chronic dysentery, varying widely in severity. Colic, bloody diarrhea, malaise and weight loss have been described. Prognosis is usually good except in persons debilitated by other disease or by senility, in whom mortality may vary from 5 to 30 per cent.

The presence of B. coli in the urinary tract is considered a great rarity, and authentic reports are scanty. Pathogenicity in this site seems to be nil, unless accompanied by other infection, in which event B. coli is believed to be merely an aggravating factor. The alkaline medium of the bowel is more favorable to the growth of the organism than the usually acid urine.

The route by which B. coli gains access to the urinary tract is open to some question. The organisms are known to invade lymph channels, lymph nodes and capillaries, thereby making systemic involvement possible. In cases which have been reported, however, it seems probable that retrograde infestation took place. The case of a homosexual Moroccan, exhibiting gross hematuria and discreet ulcerations of the bladder, proved to have a mixed infection of bilharziasis (schistosomiasis) and balantidiasis of the urinary bladder (Remlinger, P.; Cabanie, G., and Bailly, J.: Infection vésicale mixte à "Bilharzia haematobia" et à "Balantidium coli," *Presse méd.* **46**:1730-1731 [Nov. 23] 1938). There was no evidence of B. coli in the bowel.

It would be of considerable interest and value to elicit a history of contact, and to ascertain whether or not the colon was also involved in the cases described. In the absence of concomitant colonic infestation it is unlikely that B. coli is responsible for the symptoms.

FECAL FISTULA FOLLOWING APPENDECTOMY

To the Editor:—In *The Journal,* April 19, 1947, p. 1254, Dr. Thomas W. Kredel, Indiana, Pa., asks about fecal fistula following appendectomy.

The reply does not mention a common cause of postappendectomy fecal fistula, namely regional ileitis, which in the acute attack can simulate acute appendicitis. If the terminal ileum is not carefully examined or the disease is not recognized, a normal appearing appendix is usually mistakenly removed.

Unquestionably this disease sooner or later involves the cecum, and removal of the appendix seems to hasten or make worse already existing inflammatory changes in the cecum with resulting blow out of the appendical stump. A silk purse string suture has less chance of being followed by fistula than would a simple ligation of the stump but is no guarantee against this serious complication.

Regional enteritis has a well known symptomatology, and in the acute stage surgical intervention is not indicated.

R. M. Cunningham, M.D., Baltimore.

SENILE OSTEOPOROSIS

To the Editor:—In *The Journal* of Dec. 13, 1947, Queries and Minor Notes, two queries concerned osteoporosis of the spine. One (p. 1041) was entitled "Periodic Spasm of the Lumbar Muscles" (C. W. Atherton, M.D., Fairview, Ill), and the other (p. 1042) was entitled "Senile Osteoporosis" (M.D., California). Since both articles seem to be in the same vein, I should like to make a suggestion which was not offered in the replies. Dr. Fuller Albright, Boston, has brought out quite definitely the relationship of the endocrine system to the osteoporosis which occurs particularly in women over the age of 40 or which may occur following the cessation of menstruation. It is due specifically to the failure of formation of the protein bone matrix; consequently, calcium salts cannot be deposited as they are in the normal person. It is not necessarily due to a lack of calcium. In fact, the addition of calcium to the diet, together with vitamin D, may actually be harmful. Suggested treatment for this type of osteoporosis might be the use of androgens in doses of 25 mg. three times weekly together with estrogenic substance, about 6,000 units five times weekly or diethylstilbestrol 2 to 5 mg. per day. An adequate diet containing sufficient minerals, vitamins and calcium should be provided; however, it is hardly ever necessary to add additional calcium to the diet.

C. A. Splithoff, M.D., Oakland, Calif.

SECTION OFFICERS 1947-1948

Internal Medicine—Chairman, Cecil J. Watson, Minneapolis; Vice Chairman, James A. Green, Houston, Texas; Secretary, Walter L. Palmer, 950 East 59th Street, Chicago.

Surgery, General and Abdominal—Chairman, Burr N. Carter, Cincinnati; Vice Chairman, Warren H. Cole, Chicago; Secretary, Michael E. DeBakey, 1430 Tulane Avenue, New Orleans 13.

Obstetrics and Gynecology—Chairman, William F. Mengert, Dallas, Texas; Vice Chairman, Robert L. Faulkner, Cleveland; Secretary, Arthur B. Hunt, 102 Second Avenue S.W., Rochester, Minn.

Ophthalmology—Chairman, Everett L. Goar, Houston, Texas; Vice Chairman, Francis Heed Adler, Philadelphia; Secretary, Trygve Gundersen, 101 Bay State Road, Boston.

Laryngology, Otology and Rhinology—Chairman, Fletcher D. Woodward, Charlottesville, Va.; Vice Chairman, John R. Simpson, Pittsburgh; Secretary, J. Milton Robb, 1553 Woodward Avenue, Detroit.

Pediatrics—Chairman, Oscar Reiss, Los Angeles; Vice Chairman, Stanley Gibson, Chicago; Secretary, Margaret Mary Nicholson, 1801 Eye Street N.W., Washington, D. C.

Experimental Medicine and Therapeutics—Chairman, Walter Bauer, Boston; Vice Chairman, Dwight L. Wilbur, San Francisco; Secretary, Carl V. Moore, 600 South Kingshighway, St. Louis.

Pathology and Physiology—Chairman, Alvin G. Foord, Pasadena, Calif.; Vice Chairman, George E. Wakerlin, Chicago; Secretary, Edwin F. Hirsch, 1439 South Michigan Avenue, Chicago.

Nervous and Mental Diseases—Chairman, A. R. Vonderahe, Cincinnati; Vice Chairman, William A. Smith, Atlanta, Ga.; Secretary, Frederick P. Moersch, 102 Second Avenue S.W., Rochester, Minn.

Dermatology and Syphilology—Chairman, Henry E. Michelson, Minneapolis; Vice Chairman, Carroll S. Wright, Philadelphia; Secretary, Clinton W. Lane, 508 North Grand Boulevard, St. Louis.

Preventive and Industrial Medicine and Public Health—Chairman, Robert H. Riley, Baltimore; Vice Chairman, Oscar A. Sander, Milwaukee, Wis.; Secretary, Rutherford T. Johnstone, 727 West Seventh Street, Los Angeles.

Urology—Chairman, Reed M. Nesbit, Ann Arbor, Mich.; Vice Chairman, Earl E. Ewert, Boston; Secretary, Edward N. Cook, 102 Second Avenue S.W., Rochester, Minn.

Orthopedic Surgery—Chairman, J. Warren White, Greenville, S. C.; Vice Chairman, David M. Bosworth, New York; Secretary, Joseph S. Barr, 234 Marlborough Street, Boston.

Gastro-Enterology and Proctology—Chairman, Sara M. Jordan, Boston; Vice Chairman, William H. Daniel, Los Angeles; Secretary, Grant H. Laing, 104 South Michigan Boulevard, Chicago.

Radiology—Chairman, W. W. Wasson, Denver, Colo.; Vice Chairman, Harry M. Weber, Rochester, Minn.; Secretary, U. V. Portmann, 2020 East 93d Street, Cleveland.

Anesthesiology—Chairman, Ralph M. Tovell, Hartford, Conn.; Vice Chairman, Stuart C. Cullen, Iowa City; Secretary, John S. Lundy, 102 Second Avenue S.W., Rochester, Minn.

General Practice—Chairman, Eric A. Royston, Los Angeles; Vice Chairman, Milton B. Casebolt, Kansas City, Mo.; Secretary, Winfred B. Harm, 5884 West Vernor Highway, Detroit.

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, JANUARY—APRIL 1948

Titles have been listed or abstracts made of important articles in the following journals in the Current Literature Department of The Journal during the past four months. Any of the journals, except those starred, will be lent by The Journal to subscribers in continental United States and Canada and to members of the American Medical Association for a period not exceeding three days. Three journals may be borrowed at a time. No journals are available prior to 1937. Requests for periodicals should be addressed to the Library of the American Medical Association and should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicalsare requested). Thus most of these journals are accessible to the general practitioner.

SUBJECT INDEX

This is an index to all the reading matter in THE JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "BI," Bureau of Investigation; "E," Editorial; "C," Correspondence; "OS," Organization Section; "ab," abstracts; the star (*) indicates an original article in THE JOURNAL.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths," "Medicolegal Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M," and "S." Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For author index see page 1104.

A

A. C. S. (Bogomolets), in arthritis treatment, [Rogoff] 205—ab
AN 148, evaluation of methadon, [Troxil] *921
A. T. 10: See Dihydrotachysterol
ABBOTT—Miller Tube: See Duodenal Tube
ABDOMEN: See also Gastrointestinal Tract; Pelvis; Peritoneum
  arteriography, [Wagner] 495—ab
  Ascites: See Ascites
  cancer, surgery for, [Rhoads] 308—ab
  cancer, treatment, recent advances, [Rhoads] *306
  pain (chronic) in women, [Best] 123—ab
  Pregnancy: See Pregnancy, ectopic
  stethoscope auscultation plus air inflated balloon to locate tip of Miller-Abbott tube, [McLanahan] *35
  Surgery: See Abdomen cancer; Appendectomy; Cesarean Section; Gallbladder
ABNORMALITIES: See also Arachnodactyly: Crippled; under names of specific organs and regions as Gallbladder: Heart
  congenital malformation attributable to smallpox vaccination during pregnancy? 1009
ABORTION, artificial, discussed, Berlin, 708
  hormonal test for fetal death, [Zondek & others] *965; (correction) 1107
  Infectious, in Cattle: See Brucellosis
  multiple spontaneous, 511
ABSCESS: See Ulcers; under organ affected
ACACIA, causes fatal nephrosis with arabinosis, 557—E
ACADEMY: See under names of specific academies as American Academy; New York . Academy; Seville Academy; under list of Societies at end of letter S
ACARODERMATITIS urticarioides, grain itch, outbreak in Baltimore, 112
ACCIDENTS: See also Disability; Trauma; World War II; Wounds
  Accident Service (film review) 348
  electrocution with direct shock to brain itself, [Dickson] 723—ab
  home, statistics on, 568
  Industrial: See Industrial Accidents; Workmen's Compensation
  prevention problems, A. M. A. Committee and National Safety Council Committee to confer, 475
  rural, [MacCornack] 284—ab
  statistics (annual) on, by National Safety Council, 568
ACETYLCHOLINE, inject into brachial artery, in myasthenia gravis patients and others, [Wilson] 802—ab
  physiology of, symposium at Army Chemical Center, 884
*di*ACETYL MORPHINE: See Morphine
3-ACETYLPYRIDINE aggravates blacktongue, [Elvehjem] *918
ACHROMOTRICHIA: See Hair, gray
ACID, acetic, role in metabolism, 771—E
  acetylsalicylic, dosage, [Szucs] (correction) 196
  Amino Acids: See Amino Acids
  p-aminobenzoic, antisulfonamide activity, [Elvehjem] *918
  p-aminobenzoic, mechanism in rickettsial disease, [Rivers] 292—ab
  Ascorbic Acid and Scurvy (film review), 575
  ascorbic, ascorbemia in pulmonary tuberculosis, [Lafontaine] 951—ab
  ascorbic, complaints from excessive amounts of orange juice? 432
  ascorbic, effect on intradermal tuberculin reaction, 127
  ascorbic, in poison oak dermatitis, [Klasson] 716—ab
  ascorbic, tablets, N.N.R., (National Drug) 1049
  ascorbic, utilization, 402—E
  boric, spraying nose with, 512
  fatty, iodine number, 432
  folic, any effect on impulse transmission at myoneural junction, [Haden] 310—ab
ACID—Continued
  folic, diuretic action? [Haden] 310—ab
  folic, effect in macrocytic anemia, [Haden] 310—ab
  folic, efficacy, [Haden] 310—ab
  folic, increase neurologic relapses in pernicious anemia? [Haden] 310—ab
  folic, to combat toxicity of sulfonamides, [Elvehjem] *916
  folic, treatment, indications, [Haden] *308
  folic, treatment of anemias, [Rambert] 726—ab; [Elvehjem] *916
  folic, vs. liver extract, 772—E
  glutamic, treatment of 30 Washington mentally retarded children, 988—OS
  hydrochloric, and peptic ulcer, [Bockus] 298—ab
  hydrochloric (dilute) and low salt diet in hypertension, 809
  hydrochloric, not recommended in anemias, [Haden] 310—ab
  nicotinic deficiency and tongue lesions [Bakwin] 1112—ab
  Nicotinic, Diethylamide of: See Nikethamide
  nicotinic, in rice, [Maynard & Nelson] *1045
  nicotinic, niacin amide to prevent anorexia [illegible] [Goldstein] 950—ab
  [illegible] N.N.R., (American [illegible]
  phenylpyruvic, in urine of certain feebleminded patients, 629—E
ACIDITY, Gastric: See Stomach acidity
ACIDOSIS, Diabetic: See Diabetes Mellitus
ACNE, treatment, 955
ACOUSTICS, supersonic reproduction on gramophone records, 199
ACROMEGALY, 850
ACTINOMYCES: See also Streptomycin
  asteroides infection simulating pulmonary tuberculosis, [Glover & others] *172
ACTINOMYCOSIS in Southern California, [Robinson] 1001—ab
  of salivary glands, [Furstenberg] *3
  treatment, thymol, (reply) [Etter] 1010
ACTIVITY, Early Rising After Operation: See Convalescence
ADANON, evaluation of methadon, [Troxil] *921
ADDICTION: See Alcoholism; Morphine
ADDISON'S ANEMIA: See Anemia, Pernicious
ADENOCARCINOMAS, mucin-secreting, [Patch] *825
ADENOIDECTOMY, tonsils improve as a result? 808
ADENOMA of pituitary, [Grant] *669
  Toxic, of Thyroid: See Goiter, Toxic
ADENOMYOSIS: See Endometriosis
ADOLESCENCE, brain injury from high school boxing, 907
  cancer of uterus cervix in young girls, [Speert] 797—ab
  diabetes mellitus and arteriosclerosis in youth, [Ross] 895—C
  hay fever in high school boys, 432
  hypogenitalism at puberty; use of testosterone, [Hurxthal] *12
  obesity in, [Graham] 903—ab
  rural youth and World War II, [Friedman] 775—OS
ADOLPHUS brand foods, manufacturer fined, Ariz., 940
ADRENALIN: See Epinephrine
ADRENALS, cortex extract treatment of chronic brucellosis, [Griggs] *911
  Cortex Hormone (Crystalline): See Desoxycorticosterone
  cortical substances, effective for what conditions, [Thompson] 320—ab
  hemorrhage in monocytic leukemia, [Lauckner] 723—ab
  Hormone (sympathetic): See Epinephrine
  what's new in endocrinology, [Thompson] *317
ADVERTISING Council, Inc., joint sponsor of "check tuberculosis" campaign, 112—E
  Federal Trade Commission surveys, 402—E
ADVERTISING—Continued
  in JOURNAL and membership in Cooperative Medical Advertising Bureau, Council statement, 399; 100—E
  of testosterone; partial quotation from Dr. W. O. Thompson's article, 558—E
AERONAUTICS: See Aviation
AEROSOL: See also Penicillin
  therapy of respiratory disease, [Bryson] 581—ab
AFRICA, one year expedition of Naval Medical Unit of U. of California, 336
  precautions before going to, 511
AGE, Adolescent: See Adolescence
  middle, blood pressure study on business men, 48
  Mother's: See Maternity
  Old: See Old Age
AGGLUTININS, autoagglutinins in hemolytic anemias, [Renner] 722—ab
  Rh Factor: See Rh Factor
  sludged blood, 556—E
AGGLUTINOGEN, Rh: See Rh Factor
AGRANULOCYTOSIS, ACUTE, esophageal stricture after, [Bryan] 800—ab
  thiouracil, [Solis] 654—ab
  treatment, penicillin plus pentose nucleotide and liver extracts, [Muller] 951—ab
AGRICULTURE: See Rural Communities
AIDES: See Medical Aides
AIR: See also Oxygen
  borne infections and ventilation, 144
  Embolism: See Embolism
  inflated balloon, test to locate Miller-Abbott tube, [McLanahan] *35
  Injection: See Pneumothorax, Artificial
  pollution, ordinance on, N. Y., 339
AIR PASSAGES: See Respiratory System
AIRPLANES: See Aviation
AIRSICKNESS, 288
ALASKA, medical conditions (replies) [Seinfeld] 347—C; [Brauner] 347—C
ALBUMIN: See Eggs, white of; Lactalbumin
  in Blood: See Blood proteins
  in Urine: See Albuminuria
ALBUMINURIA and pregnancy, 358
ALCALIGENES faecalis, bacteremia and meningitis from, [Terry] 64—ab
ALCOHOL ADDICTS: See Alcoholism
ALCOHOLISM: See also Medicolegal Abstracts at end of letter M
  blood amylase (elevated serum) in addicts, [Donzalski] 1065—ab
  chronic, treatment by spinal puncture, 70
  conference and broadcast, 702
  Fort Knox experiment, 1111
  heredity and, 849
  Industrial Conference on (first), 565
  intoxication earlier from concentrated or diluted drinks? 1009
  occupational disease of seamen, [Alcoholics Anonymous Seaman's Club] 900—ab
  research studies, 482
ALIMENTARY Tract: See Digestive System
ALLERGY; ALLERGENS: See Anaphylaxis and Allergy
ALLORHYTHMIAS, bigeminy or coupled beats, 615—ab
ALTITUDE, change in, effect on blood pressure, 908
  High: See also Aviation
  high, emptying of stomach at, [Nimeh] 582—ab
  high, life expectancy, Bolivia, 417
ALTRO Work Shops, Inc., experiment in cardiac rehabilitation of tuberculous, 123
AMBULATION, Early: See Convalescence
AMENORRHEA, cause and treatment, 1073
AMENTIA: See also Mental Disorders
  of infectious origin, penicillin in, [Zanetti] 654—ab
AMERICAN: See also Inter-American; Latin American; National; Pan American; South American; United States; list of societies at end of letter S
  Academy of General Practice, 834—OS

AUTHOR INDEX

In this Index are the names of the authors of articles which have appeared in THE JOURNAL, the names of those who have read papers before Societies as published in THE JOURNAL and those whose articles have been abstracted in the Current Medical Literature Department. The * preceding the page reference indicates that the article appeared in full in THE JOURNAL.

For subject index see page 1123.
